Aeromagnetic image (RTP) Sunday Creek

- Dominated by north-westerly striking open to tightly folded Silurian to early Devonian low-grade turbiditic metasediments (Humevale Siltstone and Melbourne Formation).
- Metamorphism coincident with the deformation during the Tabberabberan Orogeny in the Late Devonian produced lower greenschist facies assemblages, somewhat complicated by the thermal aureole of the multi-event emplaced I-type Mt Disappointment Granodiorite

Sunday Creek – Longitudinal section looking towards 000 in plane of dyke

SDDSC050 contains an 861 g/t AuEq x m cumulative intersection from 319.2 m to 840.0 m with thirteen individual veins sets identified over >0.5 km from the first to last high-grade gold intersection

Sunday Creek – Cross section looking towards 310 across plane of dyke

Sunday Creek Mineralisation is Changing at Depth

Previous drilling intersected near surface gold with antimony hosted in thinner quartz-carbonate veins

SDDSC050 core photo of tray 190 (621.13 m – 625.64 m) showing high-grade stibnite (antimony) mineralisation associated with gold in thin quartz-carbonate veins and stockworks.

We now see gold hosted in more massive quartz carbonate veins with very low grades of antimony

SDDSC050 core photo of tray 222 (757.9 m – 761.23 m) showing gold mineralisation associated with very low stibnite (antimony) and arsenic mineralisation in thick quartz-carbonate veins.

These textures (including discing) mimic other epizonal deposits at depth.
