- Dominated by north-westerly striking open to tightly folded Silurian to early Devonian low-grade turbiditic metasediments (Humevale Siltstone and Melbourne Formation).
- Metamorphism coincident with the deformation during the Tabberabberan Orogeny in the Late Devonian produced lower greenschist facies assemblages, somewhat complicated by the thermal aureole of the multi-event emplaced I-type Mt Disappointment Granodiorite

### Sunday Creek Mineralisation is Changing at Depth

# Previous drilling intersected near surface gold with antimony hosted in thinner quartz-carbonate veins

SDDSC050 core photo of tray 190 (621.13 m – 625.64 m) showing high-grade stibnite (antimony) mineralisation associated with gold in thin quartz-carbonate veins and stockworks.

# We now see gold hosted in more massive quartz carbonate veins with very low grades of antimony

SDDSC050 core photo of tray 222 (757.9 m – 761.23 m) showing gold mineralisation associated with very low stibnite (antimony) and arsenic mineralisation in thick quartz-carbonate veins.

These textures (including discing) mimic other epizonal deposits at depth.
