Targeting Premium DSO Bauxite

25th June 2014

Jeensia

The Manager Company Announcements Australian Securities Exchange Limited

Further Positive Laboratory Results received for South Johnstone Bauxite

- Total alumina ranges from 32% to 38% Al203
- XRF Analytical Results confirm historical alumina results
- <u>Planning for feasibility study is underway</u>
- <u>Current review of off-take options</u>

Queensland Bauxite Limited (ASX:QBL) is pleased to announce that X-ray Fluorescence (XRF) results have been received for a selection of drill samples from our South Johnstone Bauxite Project in Queensland.

This work provides a preliminary insight into the nature of the South Johnstone bauxite that highlights the relatively high iron content (25 to 31% Fe2O3) with high water content (18.9 to 23.2% LOI). The high LOI relative to alumina is significant as it indicates that the bauxite mineralisation is likely to be mostly gibbsite. This is the preferred form of bauxite as it is easier to process than non-gibbsitic bauxite. Samples are currently being tested using X-Ray Diffraction (XRD) to confirm their mineralogy.

The total alumina lies in the range from 32% to 38% Al2O3 and these results compare directly with the results obtained by Carpentaria Exploration Company

(CEC) of 31% to 37% Al2O3, reported by Znebejanek (1961). The location of the CEC drill holes are shown on Figure 1 (see Additional Information below).

Feasibility study

The Company is undertaking an independent feasibility study to evaluate early mining options at South Johnstone and to establish production targets and anticipated cash flow to the Company.

Off take options

A review of off take options is underway. Queensland Bauxite will advise the market regarding the progress of off-take discussions on the bauxite as and when required.

Yours Sincerely

Inuig Seldwan

Pnina Feldman Chairperson Queensland Bauxite Limited

XRF Analytical Results from South Johnstone Drilling

Ten samples from 5 drill holes scattered across the Atherton Basalt target were analysed to determine elemental oxide percentages (by ALS using X-Ray Fluorescence - XRF). The location of the drill holes chosen are shown on Figure 1, the assumptions and methodology used are shown in JORC Table 1, and the results for each sample shown in Table 2.

This work allows a preliminary insight into the elemental make-up of the South Johnstone bauxite and its water content. The key oxides present are Al2O3 (32–38%), Fe2O3 (25-31%), SiO2 (3.0-15.9%), TiO2 (4.1-5.6%), P2O5 (0.46-1.17%), MnO (0.08-0.45%), MgO (0.07-0.45%) and Loss on Ignition LOI (18.9-23.2%). Two of the samples chosen of XRF analysis (SJAC 013 0.0-0.5 & SJAC 019 1.0 - 2.0) were sub cut-off grade bauxite (i.e. with avail Al2O3 <20% & Rx SiO2 >10%). A comparison between total alumina and available alumina, and total silica and reactive silica is shown in Table 3.

Table 3: Comparison between Total and Available Alumina and Total and Reactive Silica

JORC Code, 2012 Edition – Table 1

Section 1 Sampling Techniques and Data

(Criteria in this section apply to all succeeding sections.)

Criteria	JORC Code explanation	Commentary
Sampling techniques	 Nature and quality of sampling (e.g. cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc.). These examples should not be taken as limiting the broad meaning of sampling. Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used. Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (e.g. 'reverse circulation drilling was used to obtain 1 m samples from which 3 kg was pulverised to produce a 30 g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g. submarine nodules) may warrant disclosure of detailed information. 	 Air core drilling of vertical holes to an average depth of 7.5 m was carried out to recover 0.5 m sample lengths downhole (holes SJAC 001 to 015) and 1 m sample lengths (holes SJAC 016 to 060). Holes were plugged at a depth of 1m (by octoplug) and backfilled. Pulverized material from air core, was collected by cyclone, dry (damp), in a calico bag. The entire drilled sample was collected to assure an appropriate sample size. Each bagged sample weighed approx. 3 kg. All samples analysed by hand held XRF analyser (Innov-X) in the field (calibrated to a bauxite standard of known composition) to provide semi-quantitative element oxides, with a selection of samples sent for assay by ALS Minerals. In the ALS laboratory. samples were riffle split and 1000g pulverized to 85% < 75 micron then analysed for available alumina (according to process AI-LICP01) and reactive silica (Si-LIP01) using an ICP-AES instrument (Leach conditions – 1g leached in 10ml of 90gpl NaOH at 143 degrees for 30 minutes). These results were released in the company's announcement on 17 June 2014. Based on these results a further 10 samples from 5 drill holes from 4 of the Resource areas (see Figure 1) were analysed by ALS to determine elemental oxide percentages by fusion x-ray diffraction (ME-XRF13n process) and water content/loss on ignition by TGA furnace (TGA furnace). The results are shown in Table 2
techniques	 Drill type (e.g. core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc.) and details (e.g. core diameter, triple or standard tube, depth of diamond tails, face- sampling bit or other type, whether core is oriented and if so, by what 	 Air core drilling carried out to industry standard using an Underdale Proline aircore drill rig

Criteria	JORC Code explanation	Commentary
	method, etc.).	Limited
Drill sample recovery	 Method of recording and assessing core and chip sample recoveries and results assessed. Measures taken to maximise sample recovery and ensure representative nature of the samples. Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material. 	 Samples collected in calico bags labelled with hole number and depth interval, and duplicate label on an aluminium tag included in bag. Representative samples collected in chip trays labelled by hole number and interval. The entire sample interval was collected and no loss of fines was noted
Logging	 Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical studies. Whether logging is qualitative or quantitative in nature. Core (or costean, channel, etc.) photography. The total length and percentage of the relevant intersections logged. 	 Samples described geologically on site, analysed with hand-held XRF and photographed. Separation between potential bauxite (red/yellow) and weathered basalt (grey/black) was possible at this stage. Samples with high alumina and low silica as recorded on the XRF were selected for analysis. All 60 holes were logged as described providing semi- quantitative percent total elemental oxide results for Al2O3, SiO2, Fe2O3 and TiO2, over a total of 460 m.
Sub-sampling techniques and sample preparation	 If core, whether cut or sawn and whether quarter, half or all core taken. If non-core, whether riffled, tube sampled, rotary split, etc. and whether sampled wet or dry. For all sample types, the nature, quality and appropriateness of the sample preparation technique. Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples. Measures taken to ensure that the sampling is representative of the in situ material collected, including for instance results for field duplicate/second-half sampling. Whether sample sizes are appropriate to the grain size of the material being sampled. 	 Bagged samples were not subsampled. Samples were prepared by ALS to industry standards according to the techniques described above in sampling techniques Material soft and friable, grain size fine.
Quality of assay data and laboratory	 The nature, quality and appropriateness of the assaying and laboratory procedures used and 	 Samples were analysed by ALS Minerals according to their industry standards. Results for weight percent oxides presented

בס"ד

n...

Oueensland

Criteria	JORC Code explanation	Commentary
tests	 whether the technique is considered partial or total. For geophysical tools, spectrometers, handheld XRF instruments, etc., the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc. Nature of quality control procedures adopted (e.g. standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (i.e. lack of bias) and precision have been established. 	 to 0.01% accuracy. Limited A QC certificate (BR14078034) was issued by ALS for the low temperature leach containing 2 standards, 2 blanks and 2 duplicate samples. A QC certificate (BR14086033) was issued by ALS for total oxide weight percent by fusion XRF and LOI by TGA furnace containing 4 standards, 1 blanks and 3 duplicate samples. These certificates show acceptable levels of accuracy (i.e. lack of bias) and precision have been established
Verification of sampling and assaying	 The verification of significant intersections by either independent or alternative company personnel. The use of twinned holes. Documentation of primary data, data entry procedures, data verification, data storage (physical and electronic) protocols. Discuss any adjustment to assay data. 	 Sampling was carried out by independent laboratory ALS Twinned sampling was carried out (SJAC 002 and 003) as detailed below and preliminary experiments carried out to test continuity at a distance between holes of 100m and 200m. Results stored by ALS Minerals and in two places in the Company's in-house system Assay results are presented as reported with no adjustment.
Location of data points	 Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation. Specification of the grid system used. Quality and adequacy of topographic control. 	 Drill hole collars were located using handheld GPS (accuracy 5 m) Coordinates recorded in GDA94 Topographic control to <u>+</u> 10mprovided by 1:100,000 topographic sheets; Atherton 7963, Bartle Frere 8063, Ravenshoe 7962 and Tully 8062; contour elevation interval 20m.
Data spacing and distribution	 Data spacing for reporting of Exploration Results. Whether the data spacing and distribution is sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied. 	EPM18463 was drilled at a spacing varying between 100m and 5km within the target geological unit (Atherton Basalt Terrain), and at a spacing of 100m to 1.5km surrounding and within the areas defined as containing bauxite resource. The deposit is a surficial deposit formed on flat-lying to gently undulating topography giving reasonable confidence to interpolate geology from hole to hole.

Criteria	JORC Code explanation	Commentary
	 Whether sample compositing has been applied. 	Samples were analysed from holes in Area A (SJAC 014), Area D (SJAC 023), Area I (SJAC 052) and Area J (SJAC 019). A below cut-off bauxite sample from SJAC 013 was also analysed. Total weight percent oxides presented in Table 2. Total and available alumina results and total and reactive silica results are compared in Table 3.
	•	No sample composting has been applied
Orientation of data in relation to geological structure	• Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known, considering the deposit type.	• The deposit is considered as a planar horizontal sheet of approximately 1 to 3 m thick located at surface (surficial weathered deposit developed on flow basalts of the Atherton Province.
	• If the relationship between the drilling orientation and the orientation of key mineralised structures is considered to have introduced a sampling bias, this should be assessed and reported if material.	 Shallow vertical drilling was carried out along the network of roads crossing the deposit sampling the mineralisation at right angles (i.e. yielding a true thickness).
Sample security	• The measures taken to ensure sample security.	• Samples were shipped to the company's storage facility (locked and alarmed) in Inverell, NSW, and there stored on pallets prior to shipment by TNT road transport to ALS minerals in Brisbane.
Audits or reviews	• The results of any audits or reviews of sampling techniques and data.	• Samples were shipped to the company's storage facility (locked and alarmed) in Inverell, NSW, and there stored on pallets prior to shipment by TNT road transport to ALS minerals in Brisbane.

Section 2 Reporting of Exploration Results

Criteria	JORC Code explanation	Commentary
Mineral tenement and land tenure status	 Type, reference name/number, location and ownership including agreements or material issues with third parties such as joint ventures, partnerships, overriding royalties, native title interests, historical sites, wilderness or national park and environmental settings. The security of the tenure held at the 	 The Exploration Permit EPM 18463 is 100% held by Queensland Bauxite Limited The tenement is secure at the present time
	time of reporting along with any known impediments to obtaining a licence to operate in the area.	
Exploration done by other parties	 Acknowledgment and appraisal of exploration by other parties. 	 Exploration in the area was carried out by Carpentaria Exploration Company in the 1960s. Znebejanek (1961) reported results for total (acid soluble) alumina rather than for alkali leach and results for silica were not reported.
		The reports are based on drilling carried out using a Proline aircore rig and the subsequent analyses. The drill holes were plotted on the Queensland Two Mile Series Sheet 403. QBL transferred these data points to a database, and these data are plotted in Figure1.
	·	 QBL total alumina results lie in the range from 32% to 38% Al2O3 and these results compare directly with the results reported by Carpentaria Exploration Company (CEC) in 1961 of 31% to 37%
Geology	 Deposit type, geological setting and style of mineralisation. 	Bauxite mineralisation occurs at surface in a weathering profile that is known from the drilling to extend from 0m to a depth of about 3m. It is found as a continuous blanket overlying flat-lying basalt flows of the Atherton Province within EPM18463. The deposit formed by weathering of the basalt surfaces with resultant leaching of silica downwards and concentration of alumina at the surface of the profile.
Drill hole Information	 A summary of all information material to the understanding of the exploration results including a tabulation of the following 	• Collar coordinates, RL, dip and azimuth for the 60 holes drilled are presented in Table 4.
	information for all Material drill holes:	Analytical data for the 10 holes analysed are presented in Tables 2 & 3
		No material data have been excluded

בס"ד

		\sim \sim				
		Queensland				
Criteria	JORC Code explanation	Commentary				
	hole collar	Limited				
	 elevation or RL (Reduced Level – elevation above sea level in metres) of the drill hole collar 					
	\circ dip and azimuth of the hole					
	 down hole length and interception depth 					
	 hole length. 					
	• If the exclusion of this information is justified on the basis that the information is not Material and this exclusion does not detract from the understanding of the report, the Competent Person should clearly explain why this is the case.					
Data aggregation methods	 In reporting Exploration Results, weighting averaging techniques, maximum and/or minimum grade truncations (e.g. cutting of high grades) and cut-off grades are usually Material and should be stated. 	 No cut-off grades have been used on these results 				
	• Where aggregate intercepts incorporate short lengths of high grade results and longer lengths of low grade results, the procedure used for such aggregation should be stated and some typical examples of such aggregations should be shown in detail.	 No aggegations have been used on these data 				
	 The assumptions used for any reporting of metal equivalent values should be clearly stated. 	 No metal equivalent values have been reported 				
Relationship between mineralisation widths and intercent	These relationships are particularly important in the reporting of Exploration Results.	 Bauxite mineralisation occurs as part of a surface weathering layer can be modelled as a thin horizontal tabular body. 				
intercept lengths	 If the geometry of the mineralisation with respect to the drill hole angle is known, its nature should be reported. 	 Vertical drill holes perforated this horizontal body at right angles, and therefore all down hole mineralisation 				
	 If it is not known and only the down hole lengths are reported, there should be a clear statement to this effect (e.g. 'down hole length, true width not known'). 	intercept lengths are true thicknesses.				
Diagrams	• Appropriate maps and sections (with	See report body for Figure 1				

בס"ד

		UUEEIISIdiiu
Criteria	JORC Code explanation	Commentary
	scales) and tabulations of intercepts should be included for any significant discovery being reported These should include, but not be limited to a plan view of drill hole collar locations and appropriate sectional views.	Limited
Balanced reporting	• Where comprehensive reporting of all Exploration Results is not practicable, representative reporting of both low and high grades and/or widths should be practiced to avoid misleading reporting of Exploration Results.	 All exploration data (ALS analytical results and their location and depth range, etc.) are presented in the report number of samples, analytical results, and ranges of values are presented and explained.
Other substantive exploration data	Other exploration data, if meaningful and material, should be reported including (but not limited to): geological observations; geophysical survey results; geochemical survey results; bulk samples – size and method of treatment; metallurgical test results; bulk density, groundwater, geotechnical and rock characteristics; potential deleterious or contaminating substances.	 Other exploration results; geologic logging of recovered samples, chip tray photographs and semi-quantitative hand-held XRF results are not included here as they are not material to the calculations presented
Further work	 The nature and scale of planned further work (e.g. tests for lateral extensions or depth extensions or large-scale step-out drilling). Diagrams clearly highlighting the areas of possible extensions, including the main geological interpretations and future drilling areas, provided this information is not commercially sensitive. 	 A shallow auger drilling program on an initial grid of 400 sq. m within the 250 sq. km Atherton Basalt target area is proposed (1600 points) to define the mineralisation within this area, with samples for the upper three metres collected at 0.5m intervals and being sent to ALS Brisbane for analysis for available alumina and reactive silica. At present the undrilled portions of the Atherton basalt remain prospective and a shallow drilling program is proposed as described above

Table 4 South Johnstone Drilling Program Collar and Hole details

Competent Person's Statement

The information in this report that relates to exploration results is based on, and fairly represent, information and supporting documentation prepared by Dr Robert Coenraads (BA Hons, MSc, PhD). Dr Coenraads is a fellow of the Australasian Institute of Mining and Metallurgy.

Dr Coenraads contracts services to QBL.

Dr Coenraads has sufficient experience which is relevant to the style of mineralization and type of deposit under consideration and to the activity which he is undertaking and to qualify as a Competent Person as defined in the 2012 Edition of the JORC Code.

Dr Coenraads consents to the inclusion in this report of the matters based on his information in the form and context in which it appears.
