TECHNICAL REPORT RECEIVED ON LATIN URANIUM PROJECTS

The Board of Cohiba Minerals Limited (Cohiba) has received a “Technical Review Report” on the Latin Uranium projects in Argentina which are being considered by Cohiba for an initial investment. The report was prepared by Mr Ariel Testi a competent person in accordance to the JORC 2012 code on the major exploration ground under an option purchase agreement (vendor agreement) held by Latin Uranium SRL (Argentina).

Cohiba has agreed to now proceed with verification drilling and other detailed exploration and geological work to determine if it will proceed with the acquisition of an initial interest in Latin or not.

It is expected that a work program proposal will be approved and commence before the end of October 2014.

The “Technical Review Report” is attached.

1 SUMMARY

The Latin Uranium projects are located in the San Juan Precordillera of Argentina within Jachal Department, approximately 100 kilometres north of San Juan city. The Huaco and Homero projects are the principal exploration targets within the 16 mineral claims, 56,097 hectares, operated by Latin Uranium SRL.

The rocks underlying the property have been mapped as Lower Paleozoic marine sequence, unconformably overlain by Upper Paleozoic marine and continental sedimentary rocks. The latter continental and minor volcanic sequences are Cenozoic. Exploration work on the uranium mineralization dates back to 1958 when National Atomic Energy Commission (“CNEA”) first recorded doing work on the property, concentrating on the Homero and Huaco projects. From 1975 to 1977, CNEA effort was followed by completion of airborne radiometric survey that defines 6 targets. The CNEA exploration team carried out small underground work and trenches. From 2007 to 2009, when S. Matellan & L. Ponce became involved in the Uranium projects, numerous companies have explored Homero project. Although encouraging high grade uranium from rock-chip-float sample results were obtained by earlier workers no mineralized zones of significant size and grade were defined.

In 2012, after having an option to purchase agreement (“Vendor Contract”) of all the ground covering Huaco and Homero projects, Latin Uranium initiated, based on airborne radiometric & magnetometric surveys processed, a systematic exploration program including rock-chip surface geochemical sampling, geological mapping, ground scintillometer traverses, induced polarization geophysics (“I.P.”) and ground magnetometer surveys.

Mineralization, at Homero project, is predominantly uraninite, with uranophane, metatorbenite, tyuyamunite and autunite. Primary sulphides such as pyrite, chalcopyrite and galena are abundant locally. Breccias at Huaco comprises of rounded clast of limestone with pervasive silicification and disseminated pyrite. Matrix is composed of fluorite, disseminated pyrite and microgranular uraninite.

In the Huaco Zone, exploration programs completed, have encourage a hidden uranium ore may related to Collapse Breccia Pipe model. The anomalous semi-circular background radiation area is 100m diameter limited by three structures that show barite-fluorite veins and breccias with pyrite and uranium content. Uranium mineralization, with associated base metals, occurs within altered breccias, accompanied by barite, fluorite, pyrite, hematite, gypsum and silica.

Homero project remains underexplored with high grade uranium assays up to 19.6% U₃O₈ in a block that may be supposed as proximal. Uranium occurrences can be observed as a stratiform trend mineralized of 30km long; however uranium is presented irregular distribution. The difficulty in exploring the project is associated with steep rock slopes that required climbing equipment and experienced climbing instructor.

2 INTRODUCTION AND TERMS OF REFERENCE

This report was commissioned by Cohiba Minerals Limited with offices at Suite 506 Level 5, 1 Princess St, Kew Victoria 3101, Melbourne, Australia and was prepared by Ariel M. Testi, M.Sc., Certified Professional Geologist. As an independent consultant, the author was asked to review the Latin Uranium SRL projects data and all pertinent historical and recent exploration work, along with data regarding regional and property geology.

In the preparation of this report, the author used of his own geological report of the area including a variety of unpublished company geological reports, Argentina Mining and Geological Survey (SEGEMAR) reports, geological maps and government claim maps. Information was also obtained from the many mineral assessment work reports filed by various companies who have completed mineral exploration programs on the Central Precordillera over the past years. A list of reports, maps and other information examined is provided in the References section (18) of this report.

Mr. Ariel Testi is an independent Consulting Geologist (AIPG-CPG#11739) with office and residence at 1589 – Jose Maria Paz St, Vicente Lopez, Buenos Aires, Argentina (1602), Tel: +54(9)1145310308, Email: 11at22@queensu.ca. He has practiced the profession continuously for 14 years. Since 2000, He has continually been involved in minerals projects for Uranium, precious and base metals in Argentina, and Chile. During his career he has taken advanced exploration, geological courses. He has worked specifically on mineral exploration in sedimentary environment for uranium, copper and silver, and additionally in intrusive-hydrothermal system for gold, nickel and copper. Mr. Ariel Testi holds a BSc in Geology from the University of La Plata, Argentina, 2000 and MSc in Mineral Exploration from Queen's University, Canada 2012. He made the personal inspection of the property that is the subject of this report in August 5 to 7, 2014 and also visited the office during August 2014. Mr. Ariel Testi was responsible for all sections of this report that was prepared for internal use of Cohiba Minerals Limited.

2.1 Source of Information

Site visit was carried out by the author from 5 to 7 August, 2014. Huaco and Homero project were visited.

3 RELIANCE ON OTHER EXPERTS

All the information in this report has been gathered by Latin Uranium SRL and previous companies. The projects comprising work in the past and it is not always easy to verify initial results. The author can attest to the fact that work carried out during the Geopshuen scouting exploration program was conducted to best industry standards of the time. Based on personal knowledge of the persons involved, I have made the assumption that a comparable situation achieved to other companies. Some confirmation sampling will, however, be required as the project advances.

For the 2013 Huaco & Homero projects, analytical work was done by Alex Stewards (Assayers) Argentina S.A., an ISO 9001: 2008 registered analytical firm. The rest of assay results were taken from SGS Argentina and ACME all certificates laboratories. Geophysical surveys were completed by J. H. Herrera Consulting, a San Juan-based geophysical contracting firm with experience in Induced Polarization and Exploration. Surface mapping and sampling was done under the supervision of J. Bastias, Exploration Manager.

For the purpose of this report, the author has relied on ownership information provided by Latin Uranium SRL. The author has not researched property title or mineral rights for the Projects and expresses no opinion as to the ownership status of the property.

4 PROPERTY DESCRIPTION AND LOCATION

4.1 Location

The Huaco & Homero Projects are situated in the San Juan Precordillera of Argentina within Jachal Department. They are located approximately 100 kms north of San Juan city, with the closest populated center being Jachal village (Fig. N° 1). The center of Huaco project is at approximate Gauss Krueger¹ (C. Inchauspe) coordinates 2545000 East and 6664000 North. The Homero project showing is centered at 2425000 East and 6601000 North.

¹.Gauss Krueger Transverse Mercator Grid metric coordinates are Campo Inchauspe, Zone 2.

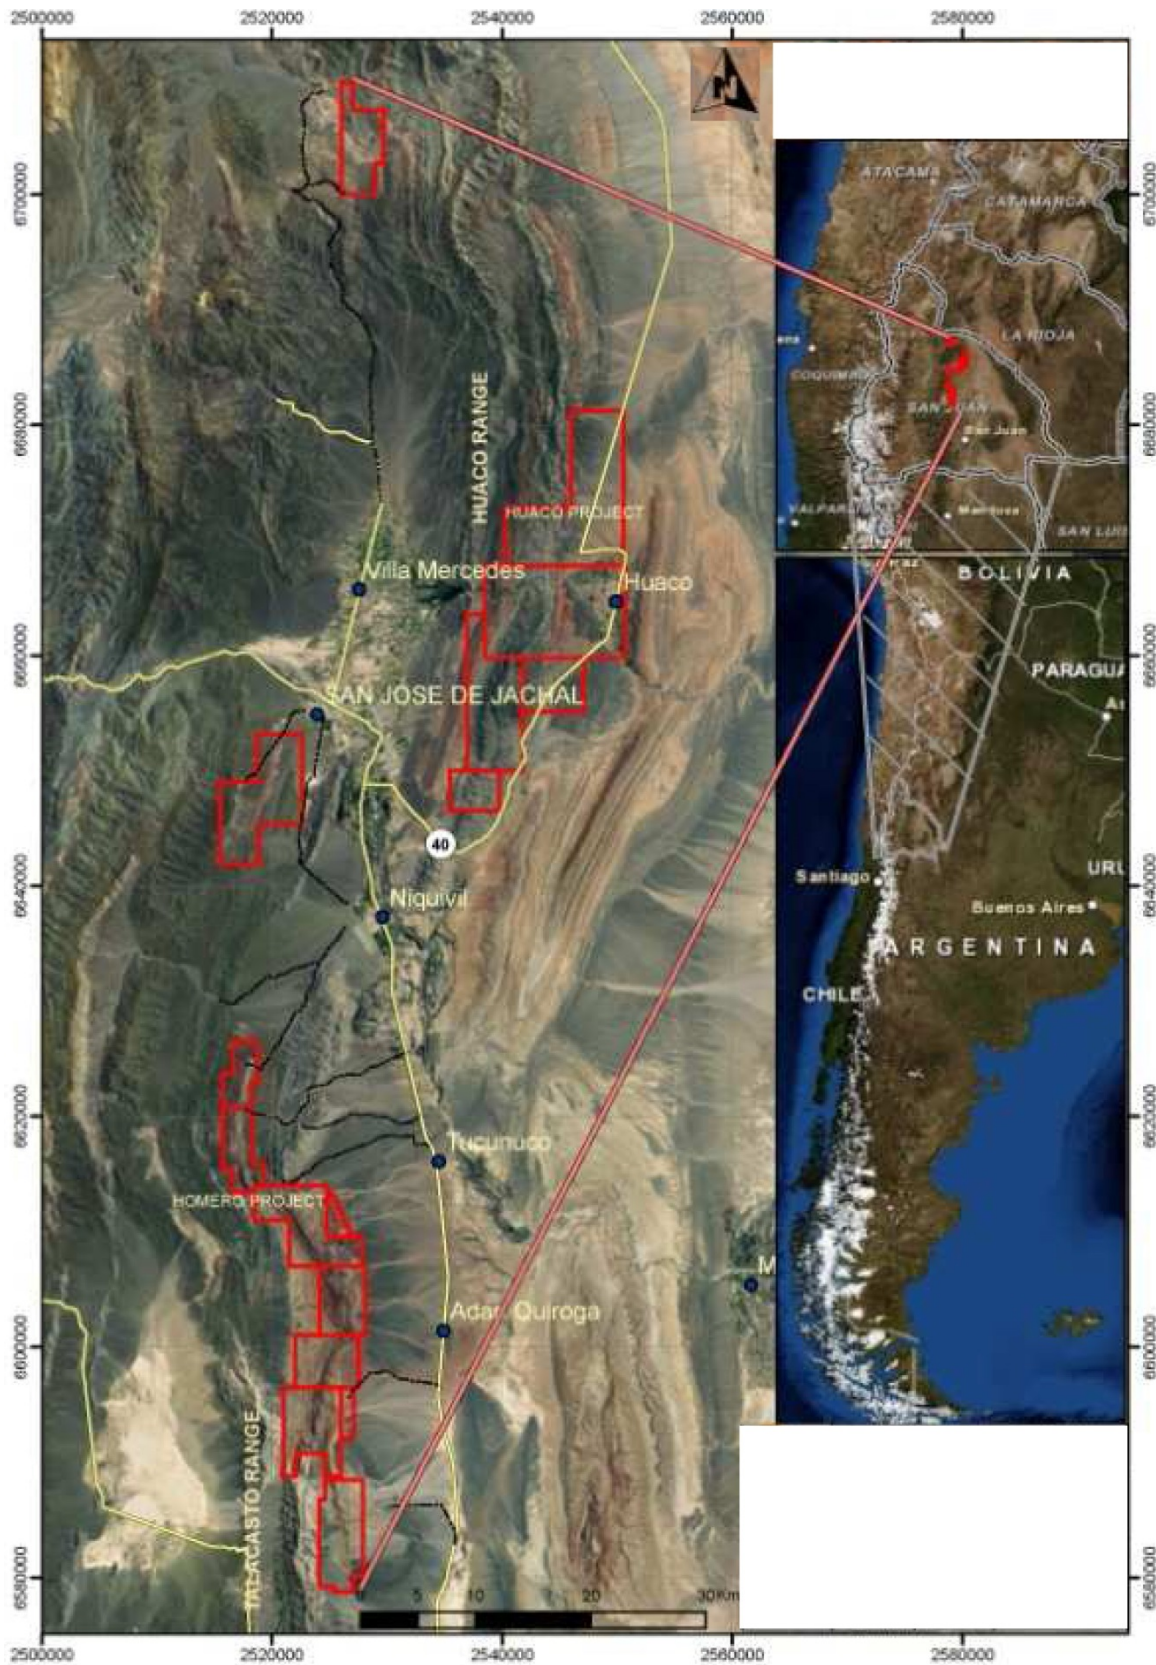

Figure 1: Location Map (Geopohuen, 2013)

4.2 Description

The Latin Uranium SRL (LU) Properties consists of sixteen (16) mineral claims covering about 56,097 hectares on the Central-Eastern Precordillera. The claims make up four blocks. The properties list is provided in Table 1 and the concession map is shown in Figures 2.

Latin Uranium has indicated to the author that the subject concessions are currently in good standing and that all required payments to the Argentinean government have been made.

A Cateo is an exploration concession and has to reduce periodically for a fixed period of time (based on the extension of the area) at a maximum period of three years.

Figure 1: Latin Uranium Tenements

4.3 Permits & Environmental Considerations

At the achievement of each stage of exploration an environmental impact study is mandatory to be submitted to the Environmental Provincial Management Unit of the San Juan Department of Mines. There are no known environmental liabilities at this time.

5 ACCESSIBILITY, CLIMATE, LOCAL RESOURCES, INFRASTRUCTURE AND PHYSIOGRAPHY

5.1 Access

Access to the area is gained via National Route 40, commonly referred to as RN40, and through different mining-seismic tracks that reach the projects. Homero properties accesses are provided by 4x4 creeks-seismic tracks from 8-10 km west of RN40. Huaco project is crosscut by Provincial Route 49 and the sector with greater sampling and mapping is surrounding the highway.

5.2 Climate

The climate in the area is continental semi-desert Cuyo region temperate with moderately warm summers and cold dry winters. Typical daytime temperature ranges are from the mid to upper 25°s Celsius in summer and 5° to -10° Celsius in winter. Precipitation averages about 100 mm. per year. Fieldwork is normally carried out throughout the year.

5.3 Local Resources

Accommodation, meals, telephone and Wifi are available at San Jose de Jachal city, approximately 25 kms west of the Huaco project. At the locality there are gas stations, covered storage and local supplies services. A Regional Hospital, grocery store and school are located in San Jose de Jachal.

Both unskilled labourers and skilled personnel trained at the Gualcamayo Mine are available at nearby San Jose de Jachal Village.

5.4 Physiography

The projects lie in the eastern side of Central Precordillera, at elevations that range from approximately 900 m to 1,700 m. The topography varies from extreme rugged topography to steep mountain valleys.

6 HISTORY

This section is largely reference from Videla, 2010.

6.1 Regional History

The first recorded exploration work carried out in the area was in 1958, when the Geological Commission N° 5 carried out a regional evaluation of the Homero project and identified several radioactive anomalies. After two years, National Atomic Energy Commission (CNEA) carried out follow-up exploration programs which included detail mapping and prospecting outcrop exposures. Further effort was followed in 1975 by completion of airborne radiometric survey. CNEA define 6 large anomalies at that time.

In 1977, CNEA carried out underground works and trenches. From 2007 to 2009 the projects were claimed by S. Matellan & L. Ponce and different companies had interest in the area. In 2012, Latin Uranium SRL signed an agreement with an option to purchase 100% of an extensive exploration concession at San Juan Precordillera and conducted several exploration programs in the area, concentrating its efforts on the most promising targets Huaco & Homero projects.

7 GEOLOGICAL SETTING AND MINERALIZATION

7.1 Regional Geology

The Precordillera is a fold and thrust belt that makes up the foothills of the high elevation Andes. Three morpho-structural units are recognized in the Precordillera:

- The Eastern Precordillera (only in the San Juan Province) shows thick-skinned deformation with westward vergence.
- The Central Precordillera extends from the La Rioja, through San Juan, up to the Mendoza Province and shows thin-skinned deformation with eastward vergence.
- The Western Precordillera shows a general eastward vergence.

The western and central Precordillera are a series of mainly Paleozoic ranges and linear valleys bounded by N–S east verging reverse faults. In contrast, the eastern Precordillera is made up of Paleozoic, Triassic and Cenozoic rocks with both thin-skinned and thick-skinned structures and west verging thrust faults.

The regional geology includes Lower to Middle Paleozoic marine folded sequences unconformably overlain by Upper Paleozoic to Lower Mesozoic rocks that are marine to continental sedimentary sequences. Overlaying the units largely to the eastern are Cenozoic continental sedimentary sequences (Fig. N°3).

Intrusive rocks in the San Juan Precordillera area are typically gabbros and basalts dykes, sills and plutons of Late Ordovician age. A younger intrusive suite includes dacitic to andesitic dykes that are interpreted as Cretaceous-Tertiary sequences with correlative pyroclastic units.

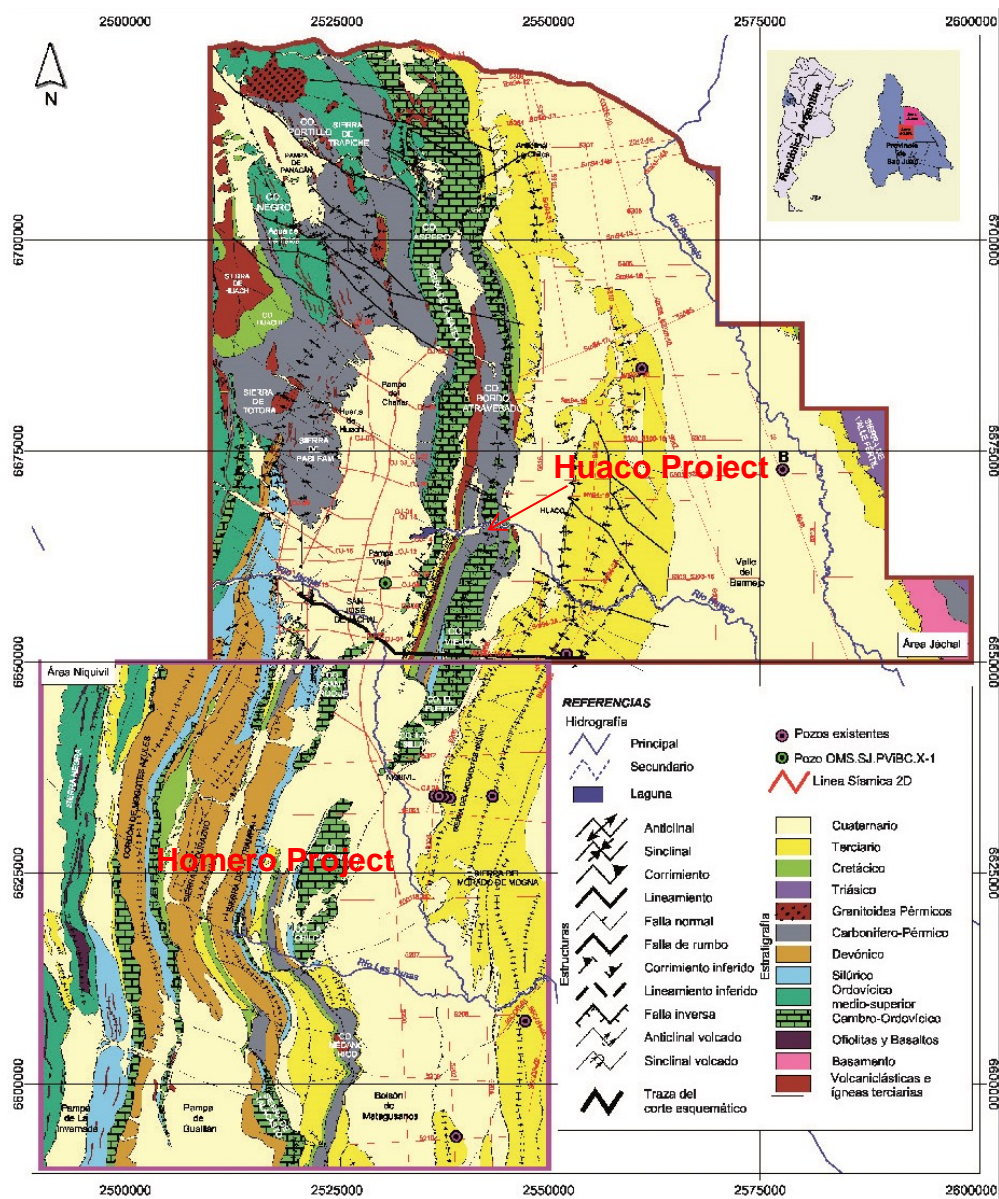

Figure 2: Regional Geology Map (Perez, 2012)

7.2 Local Geology

The eastern Huaco project, which is the focus of Latin Uranium SRL, is underlain by Lower Paleozoic limited to the carbonatic sequence overlain by Upper Paleozoic rocks and covered by Triassic and thin Cretaceous sequences. The Tertiary sequence is composed of 6000 m of eolian deposits, andesitic agglomerates, tuffaceous sandstone and andesitic basaltic flows. Cutting Tertiary rocks are uncommon andesitic dykes and irregular plugs.

Within the core project area, San Juan Formation rocks show thickly bedded Ordovician carbonate platform interbedded with minor black shales. Unconformably overlying the Carbonatic units are lacustrine sequence of the Guandacol Formation. These rocks comprise black shales, laminated siltstone and interstratified sandstones and mudstones. Finally, cutting limestone and lower part of Guandacol formation are Barite veins and hydrothermal structure-fluids-Breccia (Ba-F-Fe $\text{SO}_4\text{-S}^{2+}$ + U, Pb, Zn) inferred as Tertiary age (Fig. N° 4).

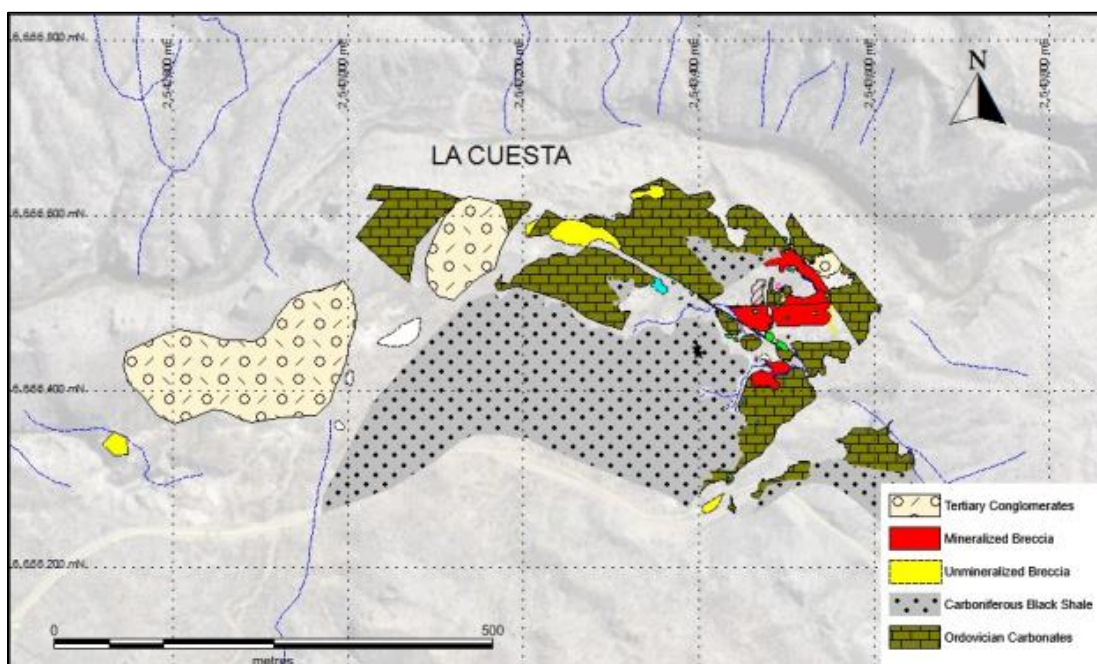

Figure 3: Huaco Project Detail Geologic Map

The southwestern Homero project is underlain by a continental red bed sequence of Carboniferous-Permian Quebrada del Volcán Group. The central portion of the project (Medano Rico sector) comprises only the upper section of Quebrada del Volcán Group, Panacán and Ojo de Agua Formations. The underlain exposed formation is composed of pebbly sandstone, coal horizon and interbedded sandstone and mudstone. Overlaying, Ojo de agua Formation comprises fine red sandstone, siltstone and mudstone.

7.3 Mineralization

Mineralization, at Homero project, is predominantly uraninite, with uranophane, metatorbenite, tyuyamunite and autunite. Primary sulphides such as pyrite, chalcocopyrite and galena are abundant locally (Fig. N° 5).

Figure 4: Mineralization Detail at Homero project

In breccia pipe deposits, uranium occurs largely as blebs, bands, small veins, and fine disseminations of uraninite. Mineralization is confined to matrix material, but may spread out into clasts. Breccias at Huaco comprises of rounded clast of limestone with pervasive silicification and disseminated pyrite. Matrix is composed of fluorite, disseminated pyrite and microgranular uraninite (Maidana, 2014).

Figure 5: Mineralized Breccia with 11796 CPS and disseminated pyrite+sulphides.

8 DEPOSIT TYPES

The principal deposit type on the Homero project-Central Precordillera is sandstone-hosted Uranium Deposit. Uranium deposits are tabular in shape, and are hosted by coarse clastics of fluvial origin overlain by shales.

Sandstone hosted uranium consist of microcrystalline uranium oxides and silicates deposited during diagenesis in localized reduced environments within fine- to medium-grained sandstone beds. Some uranium oxides are also deposited during redistribution by ground water at interface between oxidized and reduced ground. These deposits prerequisite is permeability, provided by the medium to coarse grained sandstone that are highly permeable at time of mineralization (Bleaching alteration) and subsequently restricted by cementation. Replacement of wood and other carbonaceous material is common. Roll front deposits form bow-shape lenses that cuts across bedding, at the interface between oxidized and reduced ground (Maynard, 2005).

The primary minerals are uraninite and coffinite with pyrite common in organic-rich horizons. Chlorite is common. Primary uraninite or coffinite are often oxidized to a variety of minerals, notably yellow carnotite in V-rich ores.

The sandstone hosted uranium deposits are anomalous in U, V, Mo and Se, and locally Cu and, Ag. Anomalous radioactivity from daughter products of uranium can be located with scintillometers. Geophysically, sandstone hosted uranium deposits typically display low magnetic susceptibility in and near tabular ore bodies.

Tectonic-lithologic controlled uranium deposits take place in sandstones close to a permeable fault zone which cuts the sandstone/mudstone sequence. Mineralization defines finger-shaped ore zones along the permeable sandstone horizon.

A secondary deposit type with potential to occur in Huaco project is Solution-Collapse Breccia Pipe Deposit.

The description indicates that these deposits consist of pipe-shaped breccia bodies formed by solution collapse and contain uraninite and associated sulfide and oxide minerals of Cu, Fe, V, Zn, Pb, Ag, As, Mo, Ni, Co, and Se.

Breccia pipes are comprised of three features:

- Structurally shallow depression at surface (designated by some as a collapse cone);
- Breccia pipe which underlies the structural depression,
- Annular fracture rings which occur outside, but at the margin of the pipes.

Annular fracture rings are commonly, but not always, mineralized. The structural depression may range in diameter up to 700m. or more, whereas breccia pipe diameters range up to about 200 m.; the normal range is 50 m. to 100 m.

9 EXPLORATION

9.1 Exploration History

Mineral exploration activities have been carried out in the uranium occurrences since early 1958. Activities were originally conducted by National Atomic Energy Commission (CNEA) and since 2011 by the Latin Uranium SRL. They have included as a first step reconnaissance mapping, airborne radiometric & magnetometric surveys acquired and processed, ground radiometric traverses and chip sampling of most promising outcrops. Selected targets have been the subject of detailed geological mapping, channel sampling of outcrops, thin and polished section studies, ICP studies, and geophysical surveys (grid scintillometer; ground dipole-dipole IP / resistivity, ground magnetometry).

9.2 Huaco Project

Regional exploration by Latin Uranium comprised previous airborne magnetometer and radiometric anomalies. Exploration on the main Huaco project included geological reconnaissance.

The Latin Uranium program for Huaco project is identification of prospective pipe targets, followed by shallow drilling to define pipe geometry, and deep drilling to test favorable stratigraphy in the pipes for uranium mineralization.

9.3 Homero Project

Work undertaken by LU at Homero project included geological reconnaissance, dipole-dipole IP surveys, prospect geological mapping, geochemical samples and scintillometer traverses.

Geochemical Survey

LU and previous companies collected 156 rockchip-float-talus samples from creeks in red bed sedimentary rocks. Twenty samples carried uranium values between 1000-8000ppm while another eight samples carried uranium values greater than 10,000ppm with a maximum value of 16,6% from bleached medium sandstone.

Geological Mapping

LU completed geological mapping at 1:10,000 scale over the main project area.

Geophysical Survey

IP Survey

Approximately 1400 line metres of IP dipole-dipole were surveyed using a line spacing of 200 metres and station spacing of 50 metres. The IP work identified two target areas.

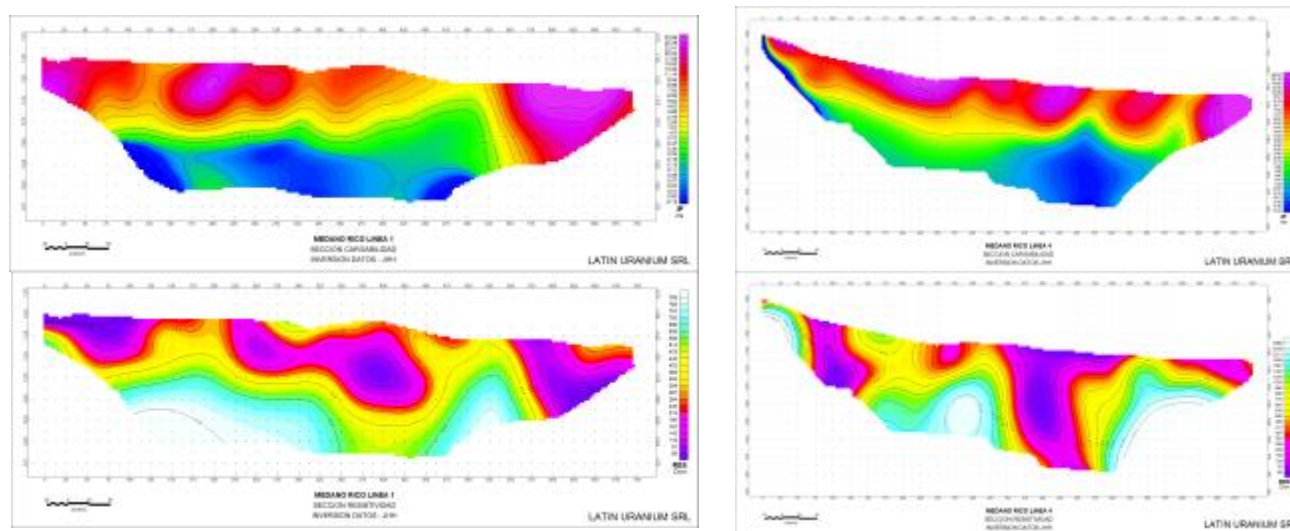

Figure7: a) Line 1 Chargeability and Resistivity. b) Line 4 Chargeability and Resistivity

Scintillometer Traverses

The traverses were documented with two scintillometers-gamma spectrometric equipment (RS125) and Bluetooth GPS due to have the geographic radiometric data. Traverses define an area of 2 x 1 km with several radiometric anomalies.

The central part of the Homero Project yielded high grade selective uranium samples, up to 19.6% U_3O_8 in a block that may be supposed as proximal. *“The uranium mineralization observed is partially restricted to ENE-WSW and minor N-S fracture systems within Panacán (Cb) and Ojo de Agua (Pm) Formations. Uranium mineralization appears to be forming envelopes of mineralization along fractures when it cut permeable units. These preliminary results encourage discovering a low tonnage / high grade uranium deposit” (Geopeluen, 2013).*

9.4 Current Exploration

Exploration is advancing to identify uranium deposits and to test several targets. This program includes ground geophysics, detailed geological mapping and surface

sampling, followed by drilling. Drilling targets are defined as complement by Satellite imagery, geophysics and geochemical surveys.

10 DRILLING

No drilling has carried out on Huaco and Homero projects.

11 SAMPLE PREPARATION, ANALYSES AND SECURITY

Samples collected by previous companies were prepared and analyzed by different laboratories using many different analytical techniques and sample preparation protocols. Furthermore, details in some reports on sample preparation and analysis are only partially summarized. Quality control measures (inserted reference materials, blanks and duplicates) are only rarely mentioned and in occasionally reports there is no indication that replicate analyses were carried out. Sample results must be used with caution, although generally the preparation and analytical techniques conformed to the industry standards of the time.

12 DATA VERIFICATION

Data verification has been accomplished by the following:

Visual inspection of alteration, rock types, and structure in outcrop and at projects on properties;

Observation in the field of more than seven times anomalous background radiation areas and spots (up to 10,000CPS), as shown by a hand-held scintillometer;

Pending reports with external lab test results that also would be confirm uranium mineralization in select samples.

Visual inspection in the field confirms the geology as typical of uranium mineralization. Boxwork iron oxides (limonite and hematite), fresh pyrite and carbonaceous material are visible in some outcrops. Identification of uranium mineralization was directly confirmed visually or by sampling by the authors in the field.

13 MINERAL PROCESSING AND METALLURGICAL TESTING

No mineral processing or metallurgical testing has been done for the projects, as the properties are still in the preliminary exploration phase, without defined uranium resources.

14 MINERAL RESOURCE ESTIMATION

There are currently no Mineral Reserves estimated for Huaco and Homero projects.

15 OTHER RELEVANT DATA AND INFORMATION

There is no additional relevant data or information.

16 INTERPRETATION AND CONCLUSIONS

The Huaco and Homero projects have strong history of uranium exploration.

Exploration work carried out on the Huaco project since 1958 has identified uranium occurrences in breccias on the Huaco properties hosted by the unconformity contact of Carboniferous black shale-Ordovician carbonates. The geologic mapping and geochemistry have improved the understanding of the geologic controls to mineralization and grade continuity. At this exploration stage, Huaco project is presented exploration programs with detail mapping, that encourage a hidden uranium ore may related to Collapse Breccia Pipe model. The anomalous semi-circular radiometric area is 100m diameter limited by three structures that show barite-fluorite veins and breccias with pyrite and uranium content. The geological characteristics of the project, including tenor and style of mineralization, host rock lithology and alteration assemblages and distribution, may be also similar to Arizona Collapse Breccia Pipe. Uranium mineralization, with associated base metals, occurs within altered breccias, accompanied by barite, fluorite, pyrite, hematite, gypsum and silica.

Homero project remains unexplored with high grade uranium anomalies up to 19.6% U_3O_8 in a block that may be supposed as proximal. Uranium occurrences can be

observed as a stratiform trend mineralized of 30km long; however uranium is presented irregular distribution. The difficulty in exploring the project is associated with steep rock slopes that required climbing equipment and experienced climbing instructor.

17 RECOMMENDATIONS

Huaco Project

A program of preliminary exploration in advance of drilling is recommended. This program should consist of preparing stratigraphic detail column of Ordovician sedimentary rocks in order to establish the collar prognosis and set the depth needed to reach the favourable sandstone-shale target. This should include grid geochemical sampling at the anomalous semi-circular radiometric area which it will be focus on pathfinder elements (Zn-Pb-Cd-Cu-V-Ag-Mo-Co-Se). This should be followed by field verification in advance of diamond drilling. Following the completion of first shallow drilling program that defined-verified pipe geometry. A deep drilling program should be design to test favorable stratigraphy in the pipe for uranium mineralization. Drillholes would be able to complete downhole geophysical surveys to define the uranium intercepts. Therefore, drillholes would maintain structural integrity.

Homero Project

Additional grids scintillometer survey, detailed geological mapping scale 1:5000 and rock chip sampling would help further define drill targets within an area of 3 x 3km around the higher uranium results.

General Proceures

LU would be established a QA/QC program and should be implemented by the exploration personnel. This involves the insertion of certified reference materials, blanks, and duplicates as a check on the accuracy and precision of the sample results.

All data compilation and information gathered by LU should be Integrated-validated in a single database which supports future interpretations and evaluations.

19 JORC COMPETENT PERSON STATEMENT

The information in this report that relates to Exploration Results is based on, information and supporting documentation compiled by Mr Ariel Testi who is a Certified Professional Geologist (AIPG-CPG#11739) with the American Institute of Professional Geologists. Mr Testi is a consulting Geologist appointed by Cohiba Minerals Limited to conduct exploration on the exploration licences held by Latin Uranium Pty Ltd. Mr Testi has sufficient experience which is relevant to the style of mineralisation and type of deposit under consideration and to the activity which he is undertaking to qualify as a Competent Person as defined in the 2012 Edition of the 'Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves'. Mr Testi consents to the inclusion in this report of the matters based on his information in the form and context in which it appears.

| Criteria | JORC Code explanation | Commentary |
|-----------------------|---|--|
| Sampling techniques | <ul style="list-style-type: none"> Nature and quality of sampling (eg cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling. Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used. Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (eg 'reverse circulation drilling was used to obtain 1 m samples from which 3 kg was pulverised to produce a 30 g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (eg submarine nodules) may warrant disclosure of detailed information. | <ul style="list-style-type: none"> Random chips samples were taken at surface outcrops, float and proximal blocks which show favourable geology, alteration and radiometric anomalies at project scale. In general, samples were partially weathered Representative samples at each sample site weigh between 0.8 and 2.5 kg. No details of previous companies' samples are known of their QAQC processes. Rock samples were sent to Alex Stewards (Assayers) Argentina S.A. (sample taken in 2013-2014), SGS Argentina and ACME (rest of the samples) all certificates laboratories where they were crushed, dried and pulverized. The analytical process comprises Aqua Regia digest with ICP-AR-42 (U&Th). |
| Drilling techniques | <ul style="list-style-type: none"> Drill type (eg core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (eg core diameter, triple or standard tube, depth of diamond tails, face-sampling bit or other type, whether core is oriented and if so, by what method, etc) | <ul style="list-style-type: none"> No drilling results are included. |
| Drill sample recovery | <ul style="list-style-type: none"> Method of recording and assessing core and chip sample recoveries and results assessed. Measures taken to maximise sample recovery and ensure representative nature of the samples. Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material. | <ul style="list-style-type: none"> No drilling results are included. |
| Logging | <ul style="list-style-type: none"> Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical studies. Whether logging is qualitative or quantitative in nature. Core (or costean, channel, etc) photography. The total length and percentage of the relevant intersections logged. | <ul style="list-style-type: none"> No drilling results are included. |

|--|--|--|
| Sub-sampling techniques and sample preparation | <ul style="list-style-type: none"> • If core, whether cut or sawn and whether quarter, half or all core taken. • If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry. • For all sample types, the nature, quality and appropriateness of the sample preparation technique. • Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples. • Measures taken to ensure that the sampling is representative of the in situ material collected, including for instance results for field duplicate/second-half sampling. • Whether sample sizes are appropriate to the grain size of the material being sampled. | <ul style="list-style-type: none"> • No core drilling reported. • Surface samples were not split during any part of the process. • The sample preparation of rock chips by Latin Uranium follows industry best practice in sample preparation involving oven drying, coarse crushing down to #10 followed by pulverisation of 1Kg sample to a grind size of 95% passing 106 micron. QAQC practices by previous companies are unknown, but samples repeated by Latin Uranium SRL indicate that the original previous companies sampling results was reliable. No complete recorded of field duplicates were carried out. Although, some duplicates were taken. • Laboratory QC procedures for rock sample assays involve the use of internal certified reference material as assay standards, along with blanks, duplicates and replicates. • Uranium mineralization is filling pore space in fine conglomerate-pebbly sandstone to siltstone and bands, small veins, and fine disseminations. The samples sizes of 0.8 to 2.5kg at latin Uranium projects are considered appropriate. |
| Quality of assay data and laboratory tests | <ul style="list-style-type: none"> • The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total. • For geophysical tools, spectrometers, handheld XRF instruments, etc, the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc. • Nature of quality control procedures adopted (eg standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (ie lack of bias) and precision have been established. | <ul style="list-style-type: none"> • The quality of previous companies sample assays is unknown, although generally the preparation and analytical techniques conformed to the industry standards of the time. • Handheld spectrometric- scintillometer was utilized to detect possible surface anomalies. While this data is recorded, only independent laboratory assay results are reported here. • No external (third party) laboratory checks have been completed to date. Quality control measures (inserted reference materials, blanks and duplicates) are mentioned and in occasionally reports there is no indication that replicate analyses were carried out. |
| Verification of sampling and assaying | <ul style="list-style-type: none"> • The verification of significant intersections by either independent or alternative company personnel. • The use of twinned holes. • Documentation of primary data, data entry procedures, data verification, data storage (physical and electronic) protocols. • Discuss any adjustment to assay data. | <ul style="list-style-type: none"> • Pending reports with external lab test results of significant assay values would be verified uranium mineralization by Ariel Testi. However, this is not required at this stage of exploration. • No twinned holes were drilled. • Primary assay data for rock chips has been entered into standard Excel templates for plotting on Mapinfo-ArcMap. All previous data has been entered digitally by previous explorers and verified internally by Latin Uranium. All data was compiled into Excel spreadsheets. • There has been no adjustment to assay data. |
| Location of data points | <ul style="list-style-type: none"> • Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation. • Specification of the grid system used. • Quality and adequacy of topographic control. | <ul style="list-style-type: none"> • Surface rock chip sample locations were surveyed by using a standard hand-held GPS. Expected accuracy is +/- 5m for easting and northing and +/- 15m for elevation coordinates. No drilling results are included. • The grid system for Latin Uranium projects are Argentina Gauss Krueger Campo Inchauspe, Zone 2. • Standard government topographic maps have been used for topographic validation. |

| Criteria | JORC Code explanation | Commentary |
|--|--|---|
| <i>Data spacing and distribution</i> | <ul style="list-style-type: none"> • <i>Data spacing for reporting of Exploration Results.</i> • <i>Whether the data spacing and distribution is sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied.</i> • <i>Whether sample compositing has been applied.</i> | <ul style="list-style-type: none"> • Surface samples are targeting radiometric anomalies at various spacing. • Current reconnaissance programs are not appropriate for any sort of comment on potential geological and grade continuity. There has been insufficient exploration completed to define this material as a Mineral Resource. • No sample compositing has been done. |
| <i>Orientation of data in relation to geological structure</i> | <ul style="list-style-type: none"> • <i>Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known, considering the deposit type.</i> • <i>If the relationship between the drilling orientation and the orientation of key mineralized structures is considered to have introduced a sampling bias, this should be assessed and reported if material.</i> | <ul style="list-style-type: none"> • Surface samples were collected perpendicular to vein-breccia walls and mineralized horizon, or across zones of alteration, and are representative of the mineralization controls. • No drilling is reported. |
| <i>Sample security</i> | <ul style="list-style-type: none"> • <i>The measures taken to ensure sample security</i> | <ul style="list-style-type: none"> • For rock samples, chain of custody is managed by Latin Uranium SRL. Samples are delivered by Latin Uranium SRL personnel to Alex Steward Argentina for preparation and assay. Tracking sheets have been set up to track the progress of batches of samples. Security of previous companies samples is unknown however is considered unimportant. |
| <i>Audits or reviews</i> | <ul style="list-style-type: none"> • <i>The results of any audits or reviews of sampling techniques and data</i> | <ul style="list-style-type: none"> • Numerous repeat sampling exercises validate the sampling of previous workers. |
