Exciting Gold-Copper Target Emerges at Barkly Project

Large Scale Targets Expand Project Opportunities

- A review of historical exploration, new geochemical and gravity data has identified two large-scale high priority targets south of Tennant Minerals ("the Company") high-grade Bluebird Copper-Gold Project, east of Tennant Creek in the Northern Territory (NT).
- The **Babbler Gold Prospect** identified in 1973 by Noblex (then 'R29')[1,2], is located 7km SSE of Bluebird, some 35km ESE of Tennant Creek:
  - Located on a prominent positive magnetic anomaly, adjacent to a gravity low.
  - During the 1970's four percussion drillholes with diamond tails and two additional percussion holes partially tested the geophysical anomalies, identifying widespread gold anomalism in pyrite and chlorite altered rhyolites (felsic volcanic rocks) in drillholes over 500m apart.
  - Best historical results not previously presented include:
    - **13m @ 0.48 g/t Au from 90m**, including **7m @ 0.68 g/t Au from 94m** in DDH466.
    - **22m @ 0.42 g/t Au from 33m** including 6m @ 0.61g/t Au from 33m, **3m@ 2.91g/t Au from 71m** and 14m @ 0.31 g/t Au from 81m in DDH468.
    - **12m @ 0.57 g/t Au from 6m** including 1m @ 1.22 g/t Au from 3m, 6m @ 0.46g/t Au from 39m, 3m@ 0.51g/t Au and 453ppm Cu from 86m in DDH469.
    - DDH469 contains anomalous copper intervals of 56m @ 251ppm Cu from 49m, **including 2m @ 855ppm Cu from 72m and 2m @ 1200ppm Cu from 92m.**
  - The high level of gold anomalism in holes that are approximately 500m apart, defines a potential kilometre scale gold anomaly that offers a compelling large-scale gold-system target.
  - The area has good outcrop that comprises both volcanic and sedimentary rocks of the Paleo-Proterozoic Ooradidgee Group. The sequence is close to the contact with, and overlies, the Lower Proterozoic Warramunga Group, which hosts the majority of the known copper-gold mines and prospects within the Tennant Creek mineral field.
  - Large scale NW-SE structures intersect close to the drilled gold anomaly area.
  - Recent research by the NT Geological Survey indicates possibility of copper and gold mineralisation hosted in the untested Ooradidgee Group and the presence of VHMS deposits in the region[3].
  - The Company plans to conduct wide spaced Reverse Circulation ("RC") drilling to test this area.
- The **Wedge Copper-Gold Prospect**, identified in 1973 by Noblex (then 'R31'), is located 5km SW of Bluebird, some 35km south-east of Tennant Creek.
  - The prospect is a discrete 1.5km x 650m fault bounded block of Lower Proterozoic Warramunga Group rocks with visible ironstone and gossan development.
  - Soil targets identified significant anomalous copper, iron, bismuth.

- The Babbler Gold Prospect, the Wedge Copper-Gold Prospect as well as the recently interpreted sub-surface copper anomalism at Bluebird East[4] are priority targets for wide spaced RC drilling.
- The Company continues to progress collaboration with the Strategic Alliance of companies in Tennant Creek, seeking to finalise a scoping study for the development of Bluebird as part of a shared copper-gold processing facility in the region[5].

Tennant Minerals CEO, Vincent Algar commented; "*At Babbler, the logging of pyrite and chlorite alteration within felsic volcanics in wide-spaced diamond drillholes during the 1970s containing elevated gold values is considered highly encouraging for presence of a large gold system in the area. No significant exploration has been conducted on the project since then, possibly because the host rocks were not typical of the Tennant Creek style copper-gold mineralisation targets at the time.*
Today we are aware of other factors that significantly increase the prospectivity of Babbler. These factors include the discovery of the high-grade Bluebird copper-gold system just 7km to the north, and new research recently reported by the NT Geological Survey indicating the presence of VHMS style deposits in the Paleo-Proterozoic Ooradidgee Group at the Rover Field SW of Tennant Creek.
The rhyolites at Babbler are part of the Ooradidgee Group and lie close to the contact with the more typical host rocks for high-grade Tennant Creek Style Copper-Gold-Bismuth Mineralisation. In today's environment of high gold prices and the significant advances in treatment of gold ores, we consider the size and level of anomalism of the gold target to demand significant follow up activity."

BABBLER GOLD PROSPECT

The Babbler Gold Prospect, identified in 1973 by Noblex (then R29) is located 7km SSE of Bluebird, some 35km south-east of Tennant Creek[1,2].

The area is characterised by a sequence of west-dipping rhyolitic tuffs and flows, as well as well bedded greywacke-sandstone-siltstone units. The 1970's exploration noticed a rhyolite unit containing up to 5% by volume of pyrite box-work and a significant magnetic anomaly in the area. Percussion drilling with diamond drilling tails was completed in the area.

The prospect has good outcrop and lies in an area of volcanic rocks and sediments of the Paleoproterozoic Ooradidgee Group. The sequence is close to the contact of and overlies the Lower Proterozoic Warramunga Group that hosts all the known copper-gold mines and prospects within the Tennant Creek mineral field.

Recent research by the NT Geological Survey indicates the possibility of Ooradidgee Group hosted VHMS deposits in the region[3].

Historical exploration:

- During the 1970's four diamond drillholes and two percussion holes tested the geophysical anomalies (See Figure 3), identifying widespread gold anomalism in pyrite, chlorite altered rhyolites (felsic volcanic rocks) interpreted to be part of the Ooradidgee Group Volcanic sequence that immediately overlies the Warramunga Formation. The latter hosting most of the Cu-Au-Bi mineralisation in the Tennant Creek field.
- Historical drilling indicates gold anomalism in holes approximately 500m apart, supporting a large gold geochemical anomaly present over km^2 scale.

- Historical geochemical soil sampling yielded very low-level anomalism in transported cover and is not considered an appropriate method compared to wide spaced RC drilling, which the Company plans to conduct over the area
- Large scale NW-SE structures intersect close to the drilled gold anomaly area.
- Recent research by the NT Geological Survey indicates possibility of Ooradidgee Group hosted VHMS deposits in the region (NTGS Record 2023-010, PG Farias)[3]
- The prospect is located adjacent to a magnetic anomaly, adjacent to a gravity low.
- Table below summarise significant intercepts over 0.1 dwt (0.15 g/t) indicating anomalous gold grades in drilling over an area of 1km^2.
- Gold samples were reported by ADL in penny weights per long ton as reported in the original data. A conversion factor of 1dw/long ton = 1.530612 g/t was used to convert the gold grades. All other metal values are reported in ppm.

Table 1. Significant intersections above 0.16g/t (gold converted from logged DWT (pennyweights per long ton)). Collar information is reported in Appendix 2, JORC Table disclosures are reported in Appendix 2. Complete assay records are reported in Appendix 3. Information is converted from records contained in NTGS report CR19760001.

Commentary

The Babbler gold prospect is an attractive exploration target due to its large size and high level of gold and minor copper anomalism. Anomalous gold grades occurring in pyritic, chlorite hosted felsic volcanics (rhyolites) and tuffaceous horizons have been identified in scout drilling in the 1970's by Noblex. In some places these intervals are associated with anomalous copper. These features are well documented in NTGS reports. The mineralisation identified by this work has remained untested, due to the ongoing focus over many years on discovery models centred on the shear zones and ironstone formations of the underlying Warramunga Formation rocks. Mineralisation in the overlying felsic volcanic and tuffaceous units of the younger Ooradidgee Group were not considered. Grade levels in any anomalies such as Babbler were also considered to be too low at the time for follow up due to ongoing production demands in the area at the time.

Recent work by the NTGS (NTGS Record 2023-010, PG Farias)[3] highlights the potential and likelihood of multiple styles of precious and base metal mineralisation occurring in or at the complex contact of the Warramunga and Ooradidgee interface. In the report, this is outlined in terms of the Rover Mineral Field, host to the Rover One Copper-Gold- Bismuth deposit (Castille Resources Ltd), and multiple other deposits including two Volcanogenic Hosted Massive Sulphide (VHMS) deposits (Explorer 108 and Curiosity).

At Babbler, outcrop mapping supports the view that the contact between the overlying Ooradidgee felsic volcanic and tuffaceous sequences and the underlying Warramunga Formation sedimentary package are near the surface. As explained in the NTGS record 2023-010, this complex contact, which represents an angular unconformity, is a possible location for mineralisation. The presence of regional NW-SE structures crosscutting the Babbler prospect offers further interest.

Anomalous gold values are identified in all the drilling to date. They occur over a large area (currently over 1km^2) in drillholes over 500m apart. The unusual and widespread nature of the mineralisation begs follow up. The Company will utilise wide spaced RC drilling to determine the full area of anomalism as well as identifying horizons or structures that could host higher grades, or thick accumulations of lower grades of gold bearing material. Geophysical methods which may discriminate the high contrast unconformity which may be present in the area will also be utilised.

WEDGE COPPER-GOLD PROSPECT

The Wedge Copper-Gold Prospect, identified in 1973 by Noblex (then R31) is located 5km south of Bluebird, some 35km south-east of Tennant Creek;

Tennant exploration staff have confirmed the anomalous nature of an iron gossan outcrop identified 5km SW of Bluebird. Noted in previous exploration, this anomaly corresponds to an historical target and is supported by co-incident copper, iron, bismuth soil auger anomalies and rock chips taken by the Company in December 2024.

Summary of Exploration findings;

- The historical R31 geophysical target have been confirmed by new auger and rock chip sampling and the acquisition of new gravity.
- The Wedge prospect is located South-West of Bluebird on a 3km SSE offset of the strongly mineralised Golden Mile-Perseverance-Bluebird trend.
- The prospect is a discrete 1.5km x 650m fault bounded block of Lower Proterozoic Warramunga Formation rocks with visible ironstone and gossan development.
- Initial reconnaissance and rock chips samples were taken, returning values up to Fe 56%, Cu 150ppm, 6 ppm Ag, 112 ppm Bi.
- Soil targets were identified with anomalous Cu, Fe, Bi.
- New gravity data acquired, confirming ironstone body identified from mapping.

Follow up work at the Wedge Prospect will take place in conjunction with work to be undertaken at the nearby Babbler gold anomaly. Further mapping of structures will be undertaken, prior to planning of a shallow RC program to test the target.

Authorised for release by the Board of Directors

CAUTIONARY STATEMENT REGARDING FORWARD LOOKING INFORMATION

This release may contain forward-looking statements concerning Tennant Minerals Ltd. Forward-looking statements are not statements of historical fact and actual events and results may differ materially from those described in the forward-looking statements as a result of a variety of risks, uncertainties, and other factors. Forward-looking statements are inherently subject to business, economic, competitive, political and social uncertainties and contingencies. Many factors could cause the Company's actual results to differ materially from those expressed or implied in any forward-looking information provided by the Company, or on behalf of, the Company. Such factors include, among other things, risks relating to additional funding requirements, metal prices, exploration, development and operating risks, competition, production risks, regulatory restrictions, including environmental regulation and liability and potential title disputes.

Any forward looking statements in this release are based on the Company's beliefs, opinions and estimates of Tennant Minerals Ltd as of the dates the forward-looking statements are made, and no obligation is assumed to update forward looking statements if these beliefs, opinions and estimates should change or to reflect other future developments.

COMPETENT PERSONS DECLARATION

The information in this report that relates to exploration results is based on information compiled and/or reviewed by Mr Chris Ramsay. Mr Ramsay is the General Manager of Geology at Tennant Minerals Ltd and a Fellow of the Australian Institute of Mining and Metallurgy ('FAusIMM'). Mr Ramsay has sufficient experience, including over 25 years' experience in exploration, resource evaluation, mine geology, and development studies, relevant to the style of mineralisation and type of deposits under consideration to qualify as a Competent Person as defined in the 2012 Edition of the Joint Ore Reserves Committee ('JORC') Australasian Code for Reporting of Exploration Results, Minerals Resources and Ore Reserves. Mr Ramsay consents to the inclusion in this report of the matters based on this information in the form and context in which it appears.

ASX LISTING RULES COMPLIANCE

In preparing this announcement the Company has relied on the announcements previously made by the Company as listed under "References". The Company confirms that it is not aware of any new information or data that materially affects those announcements previously made, or that would materially affect the Company from relying on those announcements for the purpose of this announcement.

Appendix 2: JORC 2012 Table 1

JORC 2012 Edition - Section 1 Sampling Techniques and Data

(Criteria in this section apply to all succeeding sections.)

Criteria	JORC Code explanation	Commentary
Sampling techniques	*Nature and quality of sampling (e.g., cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.* *Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.* *Aspects of the determination of mineralisation that are Material to the Public Report.* *In cases where 'industry standard' work has been done this would be relatively simple (e.g., 'reverse circulation drilling was used to obtain 1 m samples from which 3 kg was pulverised to produce a 30 g charge for fire assay'). In other cases, more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (e.g., submarine nodules) may warrant disclosure of detailed information.*	The historic results shared in this statement (not previously reported by the company) are taken from verified open file reports for the historic tenements relevant to the location. The exploration results were reported as being based on industry standard work practices for key processes including drilling, sampling, assay methods, and appropriate quality assurance quality control (QAQC) measures from that time, which are clearly reported in the historic documents. The reports includes certificates and references to quality controls from the time. As specified in the tables provided the samples were taken from percussion (face hammer) and diamond drill core as reported in the open file reports prepared and submitted by qualified persons at the time. Target commodities for the drilling at the time (copper and gold) remain the same today – thus the methods were and are appropriate for the commodities of interest.
Drilling techniques	*Drill type (e.g., core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (e.g., core diameter, triple or standard tube, depth of diamond tails, face-sampling bit, or other type, whether core is oriented and if so, by what method, etc).*	Holes were drilled from -50 to -70 degrees. Percussion drilling was conducted using a 4" face sampling hammer. Diamond drilling was conducted using a NQW and BQW sizes as specified.
Drill sample recovery	*Method of recording and assessing core and chip sample recoveries and results assessed.* *Measures taken to maximise sample recovery and ensure representative nature of the samples.* *Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material.*	Percussion and Diamond core: Sample recovery was recorded by the field geologist at the time. Sample recoveries are reported as adequate for the purpose of providing a representative sample for the analysis.
Logging	*Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical studies.* *Whether logging is qualitative or quantitative in nature. Core (or costean, channel, etc) photography.* *The total length and percentage of the relevant intersections logged.*	All logging is reported as being conducted according to industry standard practice. A review of the logging information confirms this assertion.

Criteria	JORC Code explanation	Commentary
Sub-sampling techniques and sample preparation	*If core, whether cut or sawn and whether quarter, half or all core taken.* *If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry.* *For all sample types, the nature, quality and appropriateness of the sample preparation technique.* *Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples.* *Measures taken to ensure that the sampling is representative of the in-situ material collected, including for instance results for field duplicate/second-half sampling.* *Whether sample sizes are appropriate to the grain size of the material being sampled.*	As reported by the operating company at the time - all sample types, the nature, quality and appropriateness of the sample preparation technique is considered adequate for the task and as per common industry practice.
Quality of assay data and laboratory tests	*The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total.* *For geophysical tools, spectrometers, handheld XRF instruments, etc, the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc.* *Nature of quality control procedures adopted (e.g., standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (i.e., lack of bias) and precision have been established.*	Assays were conducted by ADL's assay lab at Nobles Nob Mine site using Atomic Absorption Spectrometry. High grade gold samples were analysed by fire assay. Gold samples were reported by ADL in penny weights per long ton as reported in the original data. A conversion factor of 1dwt = 1.530612 was used to convert the gold grades. All other metal values are reported in ppm.
Verification of sampling and assaying	*The verification of significant intersections by either independent or alternative company personnel.* *The use of twinned holes.* *Documentation of primary data, data entry procedures, data verification, data storage (physical and electronic) protocols.* *Discuss any adjustment to assay data.*	All significant intercepts are reviewed and confirmed by at least two senior personnel before reporting to the market. Conversions (for units only) have made to the raw assay data for gold only. The raw assay data was reported historically in pennyweights / ton and have been converted to ppm (g/t) here and recorded as such in the company's databases.
Location of data points	*Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation.* *Specification of the grid system used.* *Quality and adequacy of topographic control.*	The drill hole collars were recorded in a local grid (data provided) and were transformed into GDA94. 5 of the 6 locations have been confirmed in the field and resurveyed to compare to the transformation and prove that the drill-holes exist. The comparison between the transformation and survey reconciled well.
Data spacing and distribution	*Data spacing for reporting of Exploration Results.* *Whether the data spacing, and distribution is sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied.* *Whether sample compositing has been*	The spacing of the drill holes is illustrated on the map provided and the downhole sample intervals are recorded in the historic reports and provided in this report.

Criteria	JORC Code explanation	Commentary
	applied.	
Orientation of data in relation to geological structure	*Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known, considering the deposit type.* *If the relationship between the drilling orientation and the orientation of key mineralised structures is considered to have introduced a sampling bias, this should be assessed and reported if material.*	The orientation of sampling in terms of the dominating mineralised structures is not well known. The structure and geometry are not well understood at this stage of the investigations. The historic drilling and samples appear to be well placed across the magnetic features illustrated in this report.
Sample security	*The measures taken to ensure sample security.*	The chain of custody of the samples at the time is briefly discussed in the available reports and does not appear to have been a security issue at the time.
Audits or reviews	*The results of any audits/review of sampling techniques or data.*	None yet undertaken for this dataset

JORC 2012 Edition - Section 2 Reporting of Exploration Results

(Criteria listed in the preceding section also apply to this section.)

Criteria	*JORC Code explanation*	*Commentary*
Mineral tenement and land tenure status	*Type, reference name/number, location and ownership including agreements or material issues with third parties such as joint ventures, partnerships, overriding royalties, native title interests, historical sites, wilderness or national park and environmental settings.* *The security of the tenure held at the time of reporting along with any known impediments to obtaining a licence to operate in the area.*	The Company controls 100% of two contiguous Exploration Licences, EL 28620 and EL30701 located east of Tennant Creek. All tenure is in good standing at the time of reporting. There are no known impediments with respect to obtaining a licence to operate in the area. The Tenements are held by Colour Minerals which is a wholly owned subsidiary of Tennent Minerals.
Exploration done by other parties	*Acknowledgment and appraisal of exploration by other parties.*	Several other parties have undertaken exploration in the area between the 1930s through to the present day including Posgold, Meteoric Resources and Blaze Resources. This report details drilling and analysis carried out by another party which held the tenement at that time. (1974-1975).
Geology	*Deposit type, geological setting and style of mineralisation.*	The Barkly Project covers sediments of the Lower Proterozoic Warramunga Group that hosts all of the copper-gold mines and prospects in the Tennant Creek region. At the Bluebird prospect copper-gold mineralisation is hosted by an ironstone unit within a west-northwest striking fault. The ironstones crosscut the sedimentary sequence that mostly comprises of siltstone.
Drill hole Information	*A summary of all information material to the understanding of the exploration results including a tabulation of the following information for all Material drill holes:* *easting and northing of the drill hole collar* *elevation or RL (Reduced Level – elevation above sea level in metres) of the drill hole*	Drill hole details are provided in this report.

Criteria	*JORC Code explanation*	*Commentary*
	collar *dip and azimuth of the hole* *down hole length and interception depth* *hole length.* *If the exclusion of this information is justified on the basis that the information is not Material and this exclusion does not detract from the understanding of the report, the Competent Person should clearly explain why this is the case.*	
Data aggregation methods	*In reporting Exploration Results, weighting averaging techniques, maximum and/or minimum grade truncations (e.g., cutting of high grades) and cut-off grades are usually Material and should be stated.* *Where aggregate intercepts incorporate short lengths of high-grade results and longer lengths of low-grade results, the procedure used for such aggregation should be stated and some typical examples of such aggregations should be shown in detail.* *The assumptions used for any reporting of metal equivalent values should be clearly stated.*	All exploration results are reported by a length weighted average. This ensures that short lengths of high-grade material receive less weighting than longer lengths of low-grade material. No high-grade cut-offs are applied. Gold values were converted from pennyweights per ton to g/t (@ 1.530612g/pennyweight).
Relationship between mineralisation widths and intercept lengths	*These relationships are particularly important in the reporting of Exploration Results.* *If the geometry of the mineralisation with respect to the drill hole angle is known, its nature should be reported.* *If it is not known and only the down hole lengths are reported, there should be a clear statement to this effect (e.g., 'down hole length, true width not known').*	The structure and geometry of mineralisation are not well understood at this stage of the investigations. The historic drilling and samples appear to be well placed across the magnetic features illustrated in this report.
Diagrams	*Appropriate maps and sections (with scales) and tabulations of intercepts should be included for any significant discovery being reported These should include, but not be limited to a plan view of drill hole collar locations and appropriate sectional views.*	Figures in this report show plan views that illustrate the distribution of the drilling and samples.
Balanced reporting	*Where comprehensive reporting of all Exploration Results is not practicable, representative reporting of both low and high grades and/or widths should be practiced avoiding misleading reporting of Exploration Results.*	This report sets out the information recently discovered within historic reports and seeks to discuss this information only. Significant public reporting of the company's activities on the tenements is available from the company's public reporting from 2022 until the present.
Other substantive exploration data	*Other exploration data, if meaningful and material, should be reported including (but not limited to): geological observations; geophysical survey results; geochemical survey results; bulk samples – size and method of treatment; metallurgical test results; bulk density, groundwater, geotechnical and rock characteristics; potential deleterious or contaminating substances.*	No other new material exploration results are presented in this report. Refer to Tennant Minerals (ASX. TMS) release of 25/08/2022: "Standout Geophysical Targets to Replicate Bluebird Cu-Au Discovery" for details of the IP/resistivity survey specifications.
Further work	*The nature and scale of planned further work (e.g., tests for lateral extensions or depth extensions or large-scale step-out drilling).*	Additional drilling is planned to define and extend the mineralisation. Regional targets identified using modelling of gravity and a drone magnetic survey data as well as detailed

Criteria	JORC Code explanation	Commentary
	Diagrams clearly highlighting the areas of possible extensions, including the main geological interpretations and future drilling areas, provided this information is not commercially sensitive.	IP resistivity survey data will also be drill tested during the up-coming drilling program.

Appendix 3: Assay Information from Historical Drilling

Values below level of detection are labelled "BD"
