

SIGNIFICANT DIAMOND SAW CHANNEL SAMPLES AT LA PLATA PROSPECT

15 August 2017 - Santana Minerals Limited ("Santana") is pleased to report significant diamond saw channel results from recent field work undertaken at the La Plata Prospect within the Company's Cuitaboca Project in Sinaloa, Mexico (Figure 1).

Significant results from the recently completed surface diamond saw channel sample program included:

LPTTR-30 2.45m @ 362g/t Ag, a continuous zone including:

1.00m @ 158g/t Ag

0.85m @ 603g/t Ag

0.60m @ 362g/t Ag

and

LPTTR-31 4.60m @ 295g/t Ag, a continuous zone including:

1.00m @ 450 g/t Ag

1.00m @ 322 g/t Ag

1.00m @ 306 g/t Ag

0.90m @ 188 g/t Ag

0.70m @ 160 g/t Ag

Discussion

The La Plata prospect is continuing to advance through detailed mapping and sampling to a point where it is now approaching drill readiness. The reported results from surface channels LPTTR-30 and LPTTR-31 (shown in Figure 2) are significant as they represent a continuity of high grade surface mineralisation some 300m east of the following previously reported results:

LPTTR-19	2.00m @ 78 g/t Ag
LPTTR-19	1.00m @ 1,995 g/t Ag
LPTTR-23	5.00m @ 242 g/t Ag
LPTTR-25	7.00m @ 131 g/t Ag (including 3m @278g/t Ag)

This 300m step-out extends the potential strike length of the interpreted La Plata vein system to approximately 2km. Given the significant surface results reported to date this prospect is now the subject of detailed drill planning. It is important to note that surface channel widths along the interpreted strike length have been limited to accessible outcropping so future drilling will seek to confirm to what extent this high grade surface mineralisation occurs over wider zones at depth.

About Santana

Santana is a precious metals explorer focused on Mexico where it's primary focus is earning an initial 80% interest in the Cuitaboca Silver-Gold project in Sinaloa State. Santana also holds 100% of the Namiquipa Silver Project in Chihuahua.

Additional information about Santana and its projects is available on the website: www.santanaminerals.com

Competent Person/Qualified Person

The information in this report that relates to exploration targets, exploration results, mineral resources or ore reserve is based on information compiled by Mr Jason Beckton, who is a Member of the Australian Institute of Geoscientists. Mr Beckton is a part time consultant to Santana. Mr Beckton has sufficient experience which is relevant to the style of mineralisation and type of deposit under consideration and to the activity which he is undertaking to qualify as a Competent Person as defined in the 2012 edition of the "Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves". Mr Beckton consents to the inclusion in the report of the matters based on his information in the form and context in which it appears.

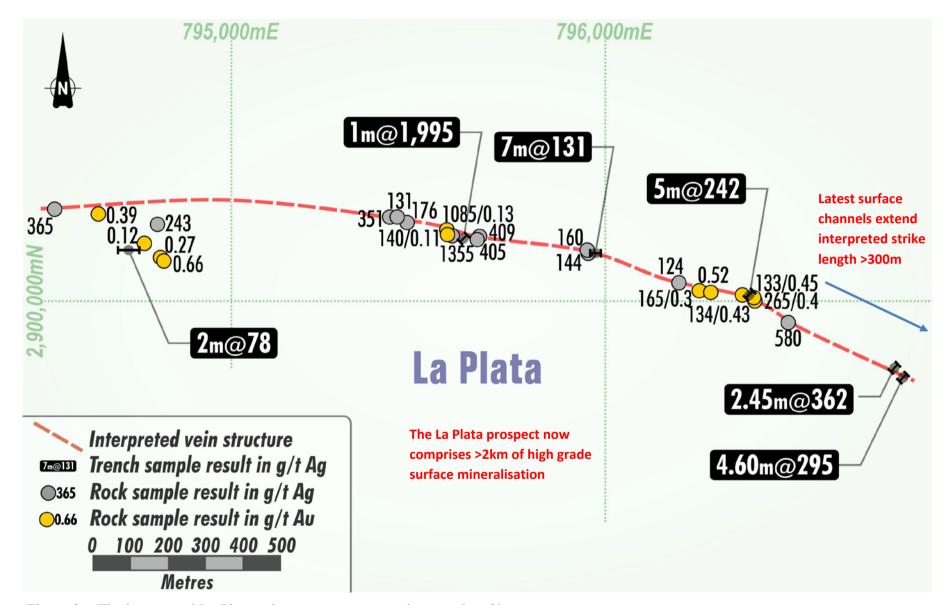

Figure 2: The interpreted La Plata vein system now extends more than 2km

JORC Code, 2012 Edition – Table 1 CUITABOCA EXPLORATION PROGRAM REPORT:

A. DIAMOND SAW CHANNEL Sampling

Section 1 Sampling Techniques and Data

Criteria	JORC Code explanation	Commentary	
Sampling techniques	 Nature and quality of sampling (eg cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling. Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used. Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (eg 'reverse circulation drilling was used to obtain 1 m samples from which 3 kg was pulverised to produce a 30 g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (eg submarine nodules) may warrant disclosure of detailed information. 	 DIAMOND SAW SAMPLING Sawn Channel samples were collected of argentite-galena-sphalerite bearing quartz veins, and zones of silicification, within Tertiary volcanics under the supervision of a qualified geologist. Sample locations were surveyed with a handheld GPS then permanently marked with an aluminum tag. Representative sawn cut samples of 2-3Kg weight were taken across the strike of the outcrop over 1 metre intervals except where noted. Intervals were cut at right angles to assist in later surveying duties. Standards inserted and photographs taken of each interval sampled which averaged 1m. 	
Drilling techniques	 Drill type (eg core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (eg core diameter, triple or standard tube, depth of diamond tails, face-sampling bit or other type, whether core is oriented and if so, by what method, etc). 	NO DRILLING IN THIS PROGRAM.	
Drill sample recovery	 Method of recording and assessing core and chip sample recoveries and results assessed. Measures taken to maximise sample recovery and ensure representative nature of the samples. Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material. 	NO DRILLING IN THIS PROGRAM.	
Logging	 Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical studies. 	Sawn Channel samples were geologically and structurally logged under the supervision of a qualified geologist.	

Criteria	JORC Code explanation	Commentary
	 Whether logging is qualitative or quantitative in nature. Core (or costean, channel, etc) photography. The total length and percentage of the relevant intersections logged. 	Sawn Channel samples were measured for metal sulphide and host quartz content and orientation.
Sub-sampling techniques and sample preparation	 If core, whether cut or sawn and whether quarter, half or all core taken. If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry. For all sample types, the nature, quality and appropriateness of the sample preparation technique. Quality control procedures adopted for all subsampling stages to maximise representivity of samples. Measures taken to ensure that the sampling is representative of the in situ material collected, including for instance results for field duplicate/second-half sampling. Whether sample sizes are appropriate to the grain size of the material being sampled. 	Sawn Channel samples were a width of at least 3cm and approximate sample support of half core NQ from diamond drilling, ie sample diameter of 56mm, being a half core sample of that.
Quality of assay data and laboratory tests	 The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total. For geophysical tools, spectrometers, handheld XRF instruments, etc, the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc. Nature of quality control procedures adopted (eg standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (ie lack of bias) and precision have been established. 	 Diamond Saw Trench Sampling Samples are stored in a secure location and transported to the ALS laboratory in Hermosillo for sample preparation of fine crush, riffle split and pulverizing of 1kg to 85% < 75μm. Pulps are analyzed by ALS Vancouver (Canada) using method code ME-ICP61a, a 33 element determination using a four acid digestion, Au-AA26.
Verification of sampling and assaying	 The verification of significant intersections by either independent or alternative company personnel. The use of twinned holes. Documentation of primary data, data entry procedures, data verification, data storage (physical and electronic) protocols. Discuss any adjustment to assay data. 	Diamond Saw Trench Sampling Laboratory CSV files are merged with GPS Location data files using unique sample numbers as the key. No adjustments made to assay data
Location of data points	 Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation. Specification of the grid system used. Quality and adequacy of topographic control. 	Diamond Saw Trench Sampling Samples are located using handheld GPS receivers. UTM projection WGS84 Zone 12N. The topographic control, using handheld GPS, was adequate for the survey.
Data spacing and distribution	 Data spacing for reporting of Exploration Results. Whether the data spacing and distribution is sufficient 	<u>Diamond Saw Trench Sampling</u> Results will not be used for resource estimation prior to any supporting drilling being carried out

Criteria	JORC Code explanation	Commentary
	to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied. • Whether sample compositing has been applied.	No compositing has been applied.
Orientation of data in relation to geological structure	 Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known, considering the deposit type. If the relationship between the drilling orientation and the orientation of key mineralised structures is considered to have introduced a sampling bias, this should be assessed and reported if material. 	Diamond Saw Trench Sampling Representative rock chip samples of 2-3Kg weight are taken across the strike of the outcrop over 1metre intervals except where noted. No bias is believed to be introduced by the sampling method. This method was employed to remove bias from previous rock chip sampling.
Sample security	The measures taken to ensure sample security.	Samples were delivered to ALS Minerals laboratory in Hermosillo by Santana geologist and were not left unattended at any time.
Audits or reviews	The results of any audits or reviews of sampling techniques and data.	No audits or reviews of the data management system have been carried out.

Section 2 Reporting of Exploration Results

Criteria	ORC Code explanation	Commentary
Mineral tenement and land tenure status	Type, reference name/number, location and ownership including agreement with third parties such as joint ventures, partnerships, overriding royalties, not historical sites, wilderness or national park and environmental settings. The security of the tenure held at the time of reporting along with any known obtaining a license to operate in the area.	to acquire 80% of the Cuitaboca Project which consists of 100% of the mining concessions: El Chapotal (126ha), San Rafael (528ha), Nuestra Senora del
Exploration done by other parties	Acknowledgment and appraisal of exploration by other parties.	 The first report of mining in the Cuitaboca area was between 1760 and 1810 with small scale mine workings. In 1883 American and English investors took control of the Cuitaboca mining operations which continued for nearly a century. Between 1974 and 1975 Servicios Industriales Penoles undertook

Criteria	JORC Code explanation	Commentary
		systematic exploration using surface and underground geological mapping and the collection of 180 samples. In 2006 Canadian-based First Majestic acquired the property after a merger with First Silver Reserve and initiated >300m of underground development at Colateral Mine which delineated a quartz-galenasphalerite vein that reported elevated Ag-Pb-Zn. First Majestic withdrew from the project in late 2008 and retained no interest.
Geology	Deposit type, geological setting and style of mineralisation.	Within the Cuitaboca project area there have been 9 discreet polymetallic low sulphidation epithermal Ag-Au veins recognised that have undergone historical manual mining. Other low sulphidation epithermal polymetallic Ag-Au vein deposits host most ore within ore shoots at the coincidence of ore controls defined as: competent host rocks, dilatant structures, higher Au-Ag grade mineralisation styles and efficient mechanisms of Au-Ag deposition. Host rocks identified as interlayered Cretaceous age andesitic lavas, volcanics and volcaniclastic rocks and lesser rhyolites of the Sierra Madre Occidental Volcanics, have been placed in a stratigraphic succession as an aid to the delineation of the andesite flows, and locally welded tuffs, recognised as the most favourable rocks to host through going fissure vein mineralisation. In the Colateral adit the transition from incompetent lapilli tuff to competent andesite host rocks corresponds to a 110% increase in Ag and 250% increase in Au grades. An exploration target occurs where competent andesite is interpreted to underlie incompetent tuff.
		Mineralised veins lie within nine NW-SE (120°TN) trending structures interpreted as listric style normal faults formed in association with regional extension within the Sierra Madre. NW trending vein dips vary from steep to moderate and may locally display a relationship to rock competency as moderate dipping structures refract to steeper dips in the more competent andesites. Steeper dips mostly host better veins within listric fault environments. Using a structural model derived from Palmarejo, no dilatant flexures were identified as changes in the strike of veins from NW towards the WNW-EW, where steep dipping veins should host core shoots. Interpretation of the regional digital terrain model suggests NNE trending transfer structures might segment the listric faults and contribute towards the localisation of mineralisation.
		The historically mined Cuitaboca polymetallic Ag-Pb-Zn (± Au) bearing epithermal quartz veins comprise dominantly banded and brecciated quartz with galena, mostly yellow sphalerite, argentite, tetrahedrite, pyrite, chalcopyrite and gangue of carbonate (calcite and rhodochrosite), barite and fluorite. The adjacent wall rocks display K-feldspar and retrograde chlorite-illite/smectite alteration

Criteria	JORC Code explanation	Commentary
Data aggregation methods	 In reporting Exploration Results, weighting averaging techniques, maximum and/or minimum grade truncations (eg cutting of high grades) and cut-off grades are usually Material and should be stated. Where aggregate intercepts incorporate short lengths of high grade results and longer lengths of low grade results, the procedure used for such aggregation should be stated and some typical examples of such aggregations should be shown in detail. The assumptions used for any reporting of metal equivalent values should be clearly stated. 	 Equivalent grades were not used in any tables or summations of the data. For intervals of less than standard 1 metre width included within 1 metre standard intercepts, a Sum Product weighted average was used.
Relationship between mineralisation widths and intercept lengths	 These relationships are particularly important in the reporting of Exploration Results. If the geometry of the mineralisation with respect to the drill hole angle is known, its nature should be reported. If it is not known and only the down hole lengths are reported, there should be a clear statement to this effect (eg 'down hole length, true width not known'). 	 All sampled intervals are reported and no lower cut is applied as campaign is a geological investigation of bulk grades of entire mineralised system.
Diagrams	 Appropriate maps and sections (with scales) and tabulations of intercepts should be included for any significant discovery being reported These should include, but not be limited to a plan view of drill hole collar locations and appropriate sectional views. 	The location and results received for diamond saw samples are displayed in the attached maps and/or Tables.
Balanced reporting	 Where comprehensive reporting of all Exploration Results is not practicable, representative reporting of both low and high grades and/or widths should be practiced to avoid misleading reporting of Exploration Results. 	 Results for all samples collected in this program are displayed on the attached maps and/or Tables.
Other substantive exploration data	 Other exploration data, if meaningful and material, should be reported including (but not limited to): geological observations; geophysical survey results; geochemical survey results; bulk samples – size and method of treatment; metallurgical test results; bulk density, groundwater, geotechnical and rock characteristics; potential deleterious or contaminating substances. 	No metallurgical or bulk density tests were conducted at the project.
Further work	 The nature and scale of planned further work (eg tests for lateral extensions or depth extensions or large-scale step-out drilling). Diagrams clearly highlighting the areas of possible extensions, including the main geological interpretations and future drilling areas, provided this information is not commercially sensitive. 	Further work is dependent on management review of the existing data.
