

ASX ANNOUNCEMENT

11 December 2019

Rumble Resources Limited (ASX: RTR) ("Rumble" or "the Company") advises that in respect of the announcement titled "Drilling Commenced at Earraheedy Zn-Pb Project" lodged on the ASX Market Announcement Platform on 10 December 2019 ("Announcement") that it retracts the references to third-party reserves and the LeadFX technical report previously included on page 4 of the Announcement. Investors should not rely on the retracted information for any investment decision in the Company. Please refer enclosed amended Announcement.

Authorisation

This announcement is authorised for release by Shane Sikora, Managing Director of the Company.

About Rumble Resources Ltd

Rumble Resources Ltd is an Australian based exploration company, officially admitted to the ASX on the 1st July 2011. Rumble was established with the aim of adding significant value to its current gold and base metal assets and will continue to look at mineral acquisition opportunities both in Australia and abroad.

Competent Persons Statement

No new drilling results are referred to in this announcement. The drilling results referred to in this announcement were first reported in the Company's announcement of 22 August 2019, titled '14 High Priority Targets at Braeside-Barramine and New Mineralisation Style defined at Earraheedy'. The Company confirms that it is not aware of any new information or data that materially affects the information included in the previous announcement. The results of the seismic survey referred to in this announcement are based on and fairly represents information and supporting documentation prepared by Mr Brett Keillor. Mr Keillor is an employee of Rumble Resources Limited and a Member of the Australasian Institute of Mining & Metallurgy and the Australian Institute of Geoscientists. Mr Keillor has provided his prior written consent as to the form and context in which the results and the supporting information are presented in this announcement. The information in this report that relates to Exploration Targets and Exploration Results is based on information compiled by Mr Brett Keillor, who is a Member of the Australasian Institute of Mining & Metallurgy and the Australian Institute of Geoscientists. Mr Keillor is an employee of Rumble Resources Limited. Mr Keillor has sufficient experience relevant to the style of mineralisation and type of deposit under consideration and to the activity which he is undertaking to qualify as a Competent Person as defined in the 2012 Edition of the "Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves". Mr Keillor consents to the inclusion in the report of the matters based on his information in the form and context in which it appears.

10th December 2019 ASX ANNOUNCEMENT

Drilling Commenced at Earraheedy Zn-Pb Project

Seismic Survey – Refined Drill targets

In November 2019 Rumble completed a seismic survey to assist with refining drill targets following the discovery of significant Zn-Pb in a previously unrecognised sandstone host unit identified in Rumble's drill program completed in August 2019 at the Earraheedy Zn-Pb project. The aim of the seismic survey was to track the significant Zn-Pb sandstone unit to surface looking to generate near surface (open-pittable depth) drill targets along with identifying zones which may host higher grade Zn-Pb within the sandstone unit.

- Seismic traverses over the main sandstone sub basins **were successful in tracking the near surface position of Zn-Pb sandstone unit** under shallow sand cover (< 10m depth) on the **south west margin** of the project with some **>13km of strike potential – Shallow (Open-Pittable Depth) Drill Targets**
- **Important:** The seismic survey was **successful in identifying multiple “channels”** developed during the formation of the Zn-Pb sandstone sub basins. The “channels” typically have coarser grained sandstone & higher porosity which would allow **space for higher grade Zn-Pb** to develop – **Compelling High-Grade Drill Targets**
 - At least **four (4) channels** have been identified, up to **500m in width**.
 - **Of note:** A single historic drill-hole (down dip of the new target zone) is **interpreted to intersect a target channel** returning **7m @ 4.85% Pb+Zn from 103m**

New Geological Model

The generation of a new geological model based on Rumble's recent drilling results, passive seismic survey and reinterpretation of a detailed gravity survey highlights the **potential for multiple large tonnage, flat lying near surface deposits** – The model will also aid in predicting and targeting the sandstone hosted Zn-Pb style mineralisation.

RC Drilling Commenced

- Rumble has commenced 500m spaced reconnaissance **vertical RC drilling to test newly defined shallow targets** (60-100m depth) in the Zn-Pb sandstone grit unit on the southwest margin of the project - **13kms of strike untested by drilling**
- The drilling will **test both sub basins** and importantly test the **newly identified “channels”** that may host the higher grade Zn – Pb mineralisation

Exploration Manager

Rumble Resources Limited (ASX: RTR) ("Rumble" or "the Company") is pleased to announce it has commenced RC drilling on the Earaheedy Project (E69/3464) targeting large tonnage, flat lying, near surface (open- pitable) sandstone hosted Zn–Pb deposits.

The program is expected to take two weeks, with assays to follow.

Earaheedy Project – Sandstone Hosted Zn-Pb

The Earaheedy project is located approximately 110km north of Wiluna, Western Australia. Rumble owns 75% of E69/3464 and Zenith Minerals Ltd (ASX: ZNC) owns 25%. Rumble has three (100% RTR) contiguous exploration licence applications ELA69/3743, ELA69/3745 and ELA69/3746 covering the extensions to the 2 sub basins identified on E69/3464 which is the inferred unconformity contact between the overlying Frere Iron Formation and underlying Yelma Formation of the Palaeoproterozoic Earaheedy Basin.

A new style of Zn-Pb mineralisation has been discovered by Rumble on the unconformity contact between the overlying Frere Iron Formation and underlying Navajoh Dolomite and shale of the Yelma Formation. Both formations are part of the lower units of the Palaeoproterozoic Earaheedy Basin. Drilling intercepted flat lying porous sandstone to grit unit that has been interpreted to be the basal unit of the Frere Iron formation that unconformably overlies the Yelma Formation. Sphalerite, galena and pyrite have replaced the matrix (pore) space within the porous sandstone grit host forming laterally extensive sulphide layers.

Two sandstone sub basins dipping to the northeast between 5 - 10° have been identified beneath the main Frere Iron Formation. The sub basins daylight under shallow sand cover along the regionally extensive Frere Iron Formation/Yelma Formation contact (unconformity) on the **southwestern margin of project**.

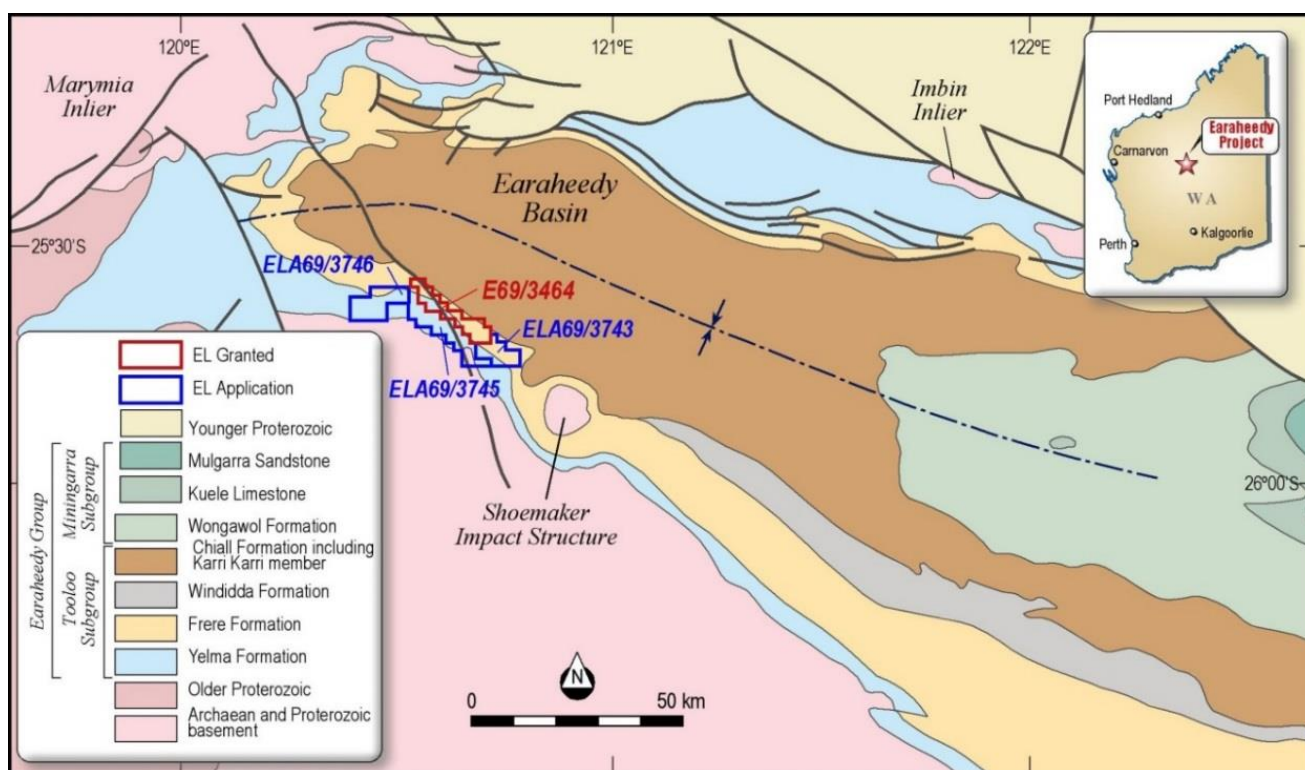

Image 2 - Regional Geology and Tenement Location Plan – Earaheedy Project

The larger sub basin (Main Sandstone Sub Basin) (See image 3) has an estimated size of **8km by 2.5km** and **is open to the southeast and northwest**. Within the Main Sandstone Sub Basin fifteen (15) diamond core and RC drill holes have intercepted the Zn Pb bearing sandstone unit. Over half of the drill holes did not pass through the sandstone and ended in mineralisation. Significant drill hole intercepts include:

- **TDH20 - 7m @ 4.85% Zn + Pb from 103m EOH in sandstone**
- **TRC47 - 6m @ 3.91% Zn, 0.39% Pb from 210.5m in sandstone**

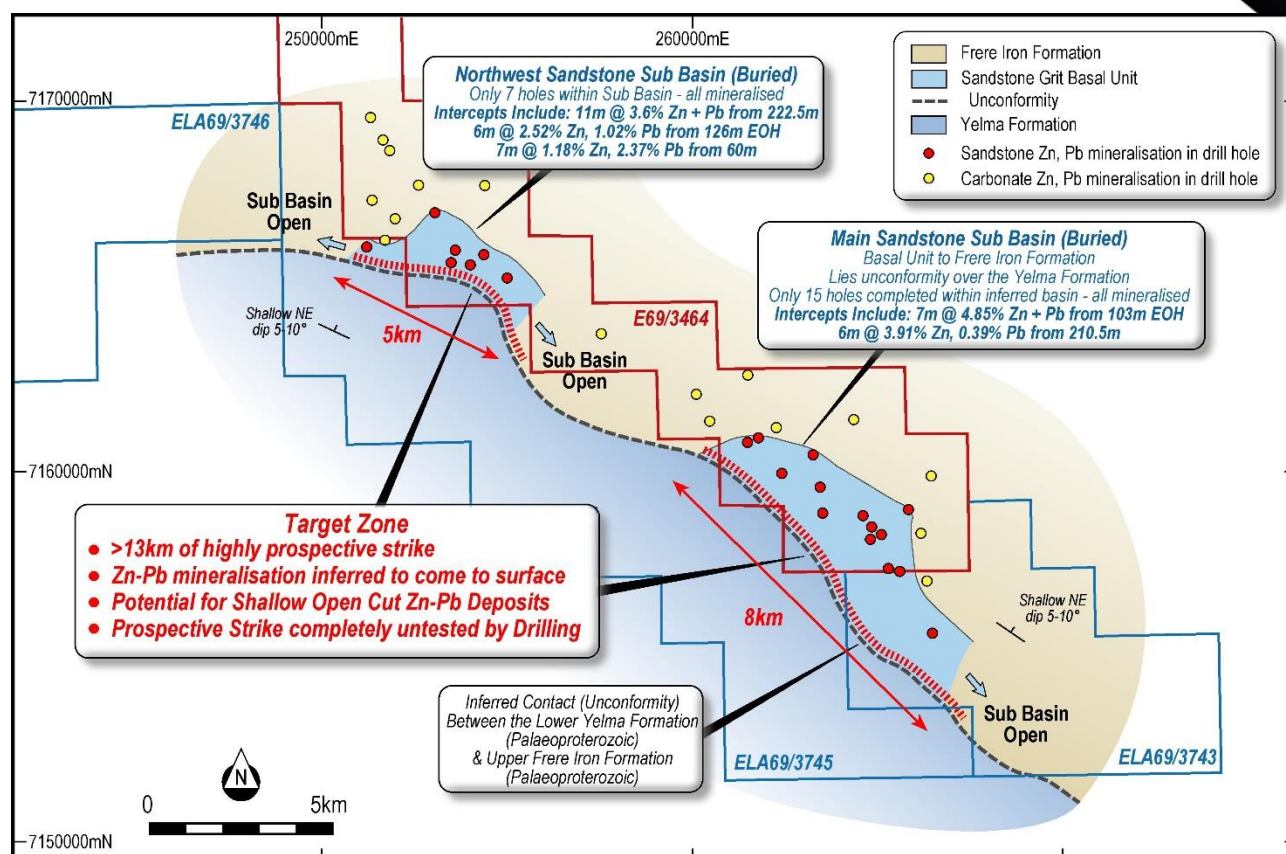

Image 3 – Highlighting the two sandstone sub basins with over 13kms of shallow drill target zones and new applications.

The smaller sub basin (Northwest Sandstone Sub Basin) (see image 3) has an area of 5km by 2km and is completely open along strike (open to the southeast and open to the west). Within the Northwest Sandstone Sub Basin seven (7) diamond core and RC drill holes have intercepted the Zn – Pb bearing sandstone unit.

Significant drill hole intercepts include:

- TDH14 – 11m @ 3.6% Zn + Pb from 222.5m in sandstone
- TRC70 – 6m @ 2.52% Zn, 1.02% Pb from 126m EOH in sandstone
- TRC65 – 7m @ 1.18% Zn, 2.37% Pb from 60m in sandstone

Over 13km of prospective strike (see image 3) of potential shallow Zn-Pb mineralized sandstone has been identified where the unconformity comes to surface. The prospective strike is completely open. All previous exploration (drill holes) has focused on MVT (Mississippi Valley Type) Zn-Pb mineralisation hosted within the

Navajoh Dolomite (upper unit of the Yelma Formation). **No drill hole has tested the near surface up-dip portion of the Zn-Pb bearing sandstone unit within the sub basins.**

The source of the Zn-Pb in the sandstone is from the underlying eroded dolomite which hosts the Zn Pb MVT mineralisation. With both sub basins, the Zn Pb (MVT) dolomite is completely eroded towards the southwest. Metal zonation is evident with Pb (galena) increasing substantially (Zn:Pb ratio decreasing) towards the southwest. Mineralisation is sphalerite, galena and pyrite. The sandstone unconformity often contains cavities and voids with large volumes of high-salinity water. Other element associations include barium and manganese.

Rumble has recently conducted a passive seismic survey to aid in delineating the potential surface projection of the prospective sandstone unit. The survey in conjunction with re-interpretation of detailed gravity has re-defined the potential strike of the combined sub basins to over 20km. Details of the survey follow below.

Regional Comparative

The Earraheedy Pb-Zn sandstone hosted mineralization has similarities with the Paroo Pb Project, owned by LeadFX Inc. (a private Canadian company), which lies 120km to the southwest of the Company's Earraheedy project.

The Paroo Pb deposit is a large supergene (predominantly Pb carbonate) deposit under shallow cover. The Earraheedy project is a sulphide system and is geologically equivalent (temporally and spatially with respect to stratigraphy) to the Paroo Pb mineralization. Some dimensions of the Paroo Pb deposit include:

- Magellan – 1600m by 900m by 12m wide;
- Cano – 850m by 430m by 7m wide;
- Pinzon – 1000m by 200m by 5m wide; and
- Cover is up to 25m

Rumble considers the Earraheedy Project to have similarities to the Paroo Pb Project, however, based on exploration to date, any mineralisation is reasonably expected to be predominantly sulphide (galena and sphalerite).

Seismic Survey (images 4 to 8)

A passive seismic survey was completed by Rumble in November 2019 over the main sandstone sub basin. The survey was designed to pass over existing drill holes (four holes) to calibrate lithological types with the primary reflectors. Four traverses across the approximate position of the sandstone sub basin were completed on 100m stations. Three traverses (PSE1, PSE2 and PSE3) were completed approximately normal to the long axis of the sub basin. Traverse PSEBL was completed parallel to the long axis of the sub basin and designed to assess the up-dip portion of the sandstone unit. **See image 4 for location of passive seismic lines.**

Interpretation of traverses PSE1, PSE2 and PSE3 indicates that passive seismic has defined the basal sandstone unit above approximately 70 – 80m depth which is the main target zone for shallow Pb – Zn mineralization. Below 80m, the primary reflector is likely the deep weathering interface (as defined by drilling). The traverses were successful in determining the up-dip and surface position of the basal sandstone.

Traverse PSEBL was conducted over a distance of approximately 6km. The primary reflector is interpreted to be the basal sandstone contact and the seismic line has delineated at least four (4) channels, each up to 500m in width. The channels potentially represent coarser grained sediments (sandstone/grit/conglomerate) with increased flow through. Based on observation of Pb-Zn mineralization (diamond drill core), increased sulphide content (galena and sphalerite) is associated with more porous sandstone facies (matrix replacement by sulphides).

Of interest is the location of historic drill-hole TRC47 (see images 4 and 6) which is interpreted to intercept a channel. TRC47 returned 7m @ 4.85% Pb + Zn from 103m in sandstone.

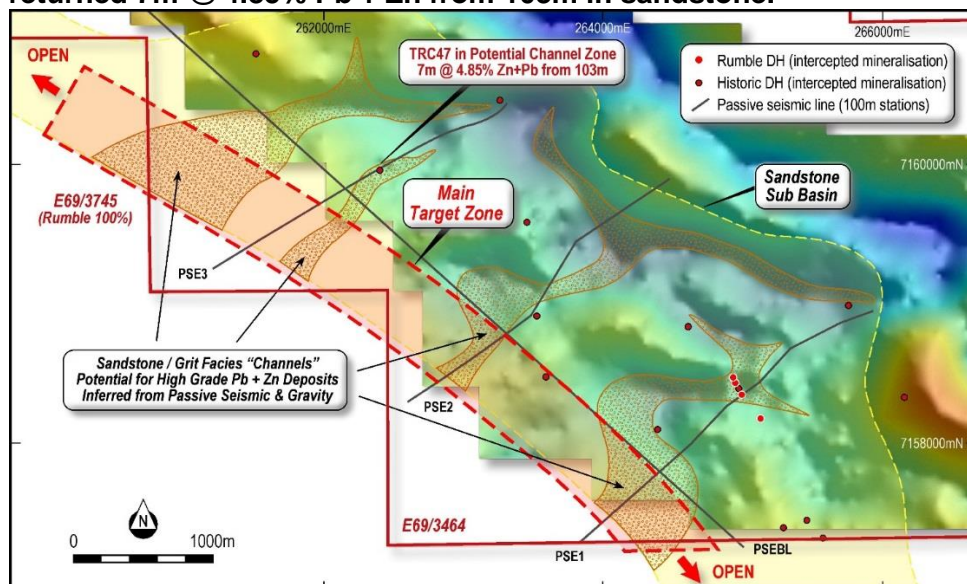

Image 4 – Main Sub Basin with Seismic Lines, Interpreted Channels and Target Zone over Gravity Image

Image 6 – Passive Seismic Traverse PSE2 with Interpretation – Note Dip of Sandstone is 5-10° NE

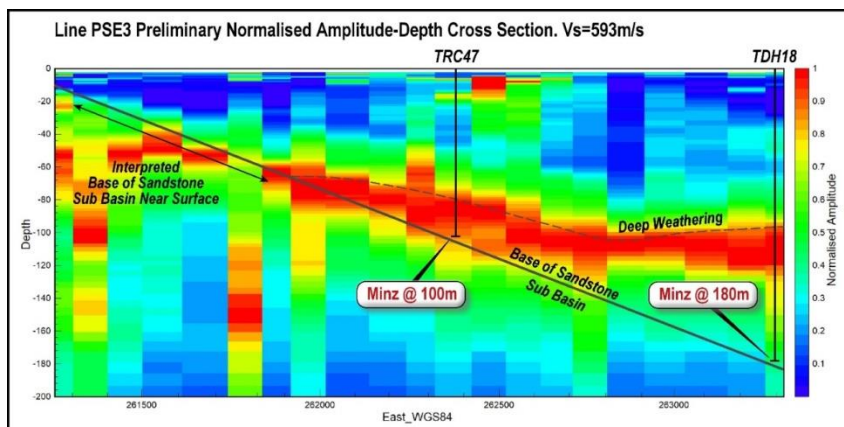

Image 7 – Passive Seismic Traverse PSE3 with Interpretation – Note Dip of Sandstone is 5-10°NE

Image 8 – Passive Seismic Traverse PSEBL with Interpretation

New Geological Model

Rumble has developed a new geological model for the Earacheedy Zn-Pb project based on recent drilling and geophysics (passive seismic survey).

The sandstone hosted Pb-Zn deposit model is considered different than the previous known Mississippi Valley Type (MVT) where earlier explorers focused on the Zn dominant disseminated/replacement carbonate hosted mineralization that occurs extensively throughout the Sweetwater Dolomite unit (upper Yelma Formation).

Rumble considers the hiatus between the Frere Iron Formation (overlying formation) and the Yelma Formation involved a stripping stage (including karstification) which partly eroded the mineralized dolomite. The early stages of sedimentation of the Frere Iron Formation developed small higher energy sub basins (coarser material) which physically stripped the dolomite which attributed to the release of a combination of physical and chemical Zn and Pb. Galena and sphalerite remobilized and re-deposited in these porous sandstone dominated sub basins.

This process likely occurred during and after the development of the Frere Iron Formation and later sedimentation cycles. The Pb:Zn ratio increases spatially away from the Zn dominant underlying dolomites.

Seismic and the re-interpretation of detailed gravity has inferred a number of channel systems developed during the formation of the sandstone sub basins.

The channels typically have coarser grained sandstone facies and porosity which would allow space for higher grade Pb – Zn mineralization to develop. Image 9 over page presents a graphical interpretation of the new geological model.

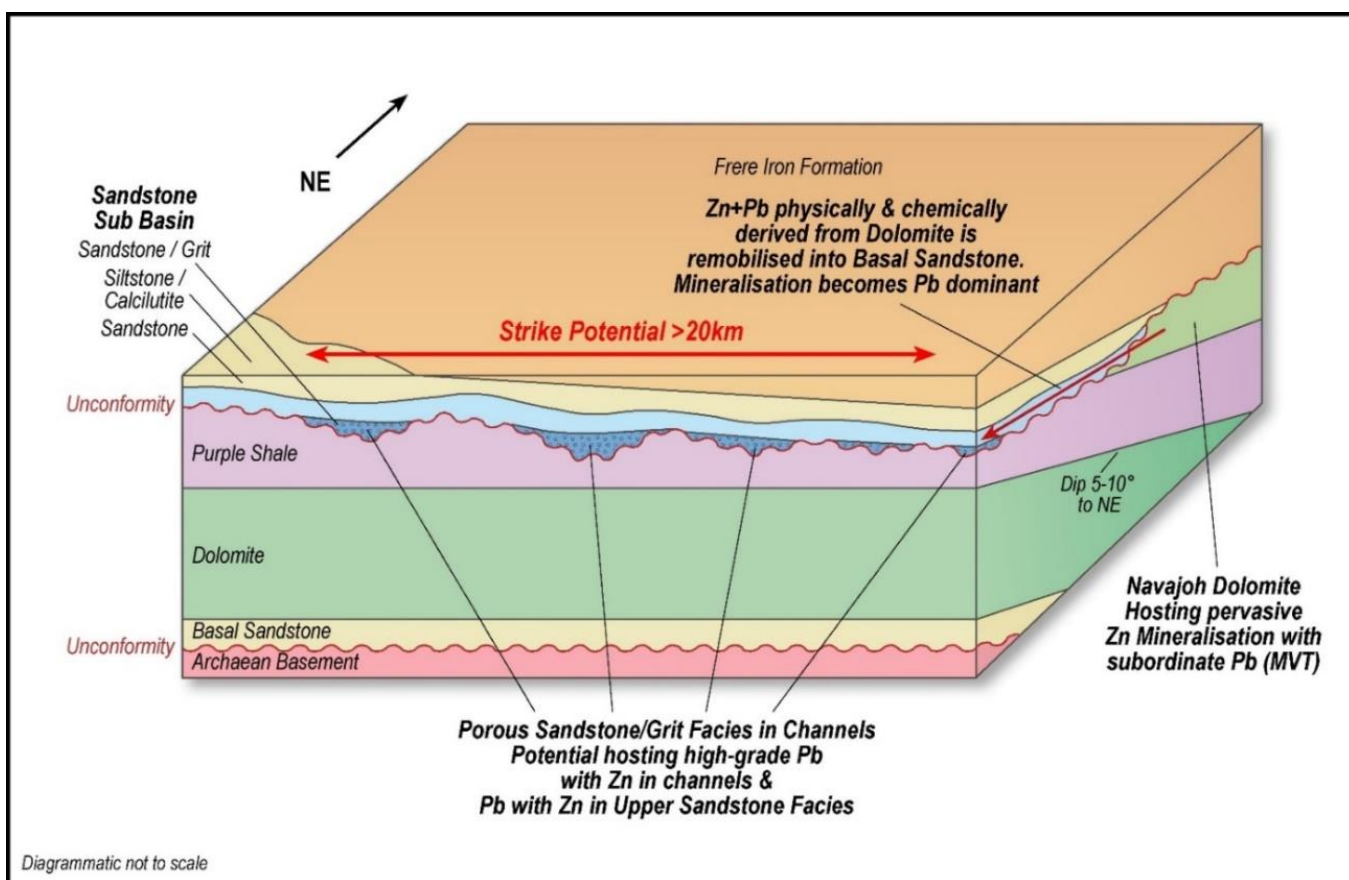

Image 9 – Geological Model for Sandstone Hosted Zn - Pb Deposits (Earacheedy Project)

RC Drill Program - Commenced

Rumble will drill test the up-dip, near surface position of the sandstone grit unit hosting the significant Zn - Pb mineralization with vertical RC drilling – 13kms of strike untested by drilling. Holes spacing is approximately 500m.

Image 3 and 4 highlight the inferred position whereby the potential mineralization surfaces under shallow sand cover. Both sub basins will be tested. In addition, the recent passive seismic survey has highlighted potential “channels” that may represent coarser grain sandstone facies which potentially hosts higher grade Pb – Zn mineralization which will be drill tested.

The drill program is targeting large tonnage, flat lying, near surface (amenable to open cut mining) sandstone hosted Zn–Pb deposits.
