

21 May 2014

The Manager Companies ASX Limited 20 Bridge Street SYDNEY NSW 2000

(16 pages by email)

Dear Madam,

### Randu Kuning High Grade Zone Extended

The directors of Augur Resources Ltd ('Augur' or 'the Company') are pleased to announce that assay results from the first two holes completed as part of the current drill program at its Wonogiri gold-copper project in Central Java, Indonesia have successfully extended a high grade gold zone intersected by previous Augur drilling in 2012.

Drill holes WDD051 and WDD052 were designed to test for extensions of higher grade gold (>1.0 g/t Au) zones previously intersected within the Randu Kuning resource area by holes WDD009 (25.0 metres of 1.03g/t Au and 0.23% Cu) and WDD050 (104.1 metres of 1.08 g/t Au and 0.25% Cu) respectively. Both WDD009 and WDD050 ended in mineralisation.

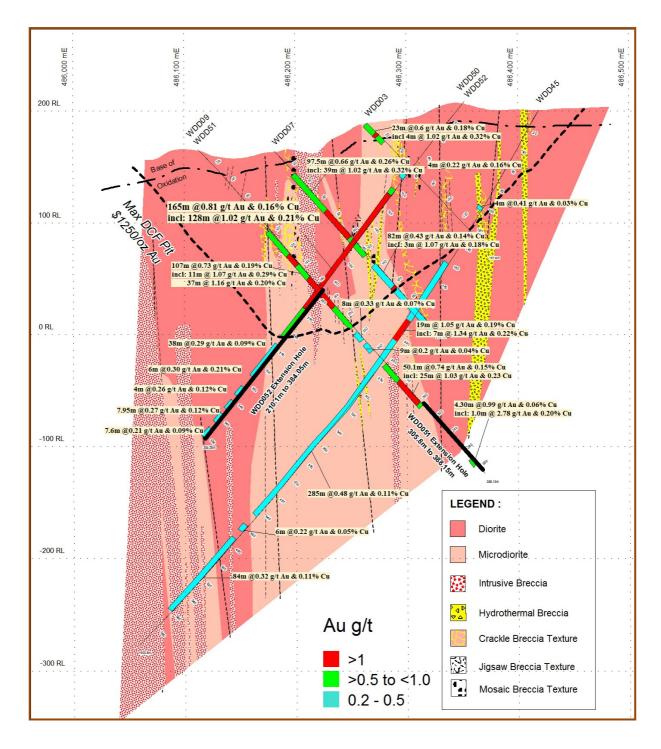

WDD052 was drilled down and began coring from the bottom of the previous hole WDD050 (210.1 metres) to a hole depth of 384.1 metres. Assay results from WDD052 returned a 60.9 metre intersection grading 0.57 g/t Au and 0.16 % Cu from 210.1 to 271.0 metres. Included in this is an 18.9 metre interval of 1.01 g/t Au and 0.16% Cu from 210.1 to 228.0 metres downhole. These intersections effectively extend the mineralised zone intersected in WDD050 to a combined (WDD050,WDD052) 165.0 metre wide mineralised zone of 0.81g/t Au and 0.16% Cu from 106.0 to 271.0 meters. Contained within this is an interval of 128.0 metres of 1.02 g/t Au and 0.21% Cu from 106.0 to 234.0 metres. The entire combined 384.1 metre length of the two drill holes averages 0.45 g/t Au and 0.13% Cu.

The 60.9 metre intersection in WDD052 lies within the conceptual open pit model prepared as part of the scoping study.

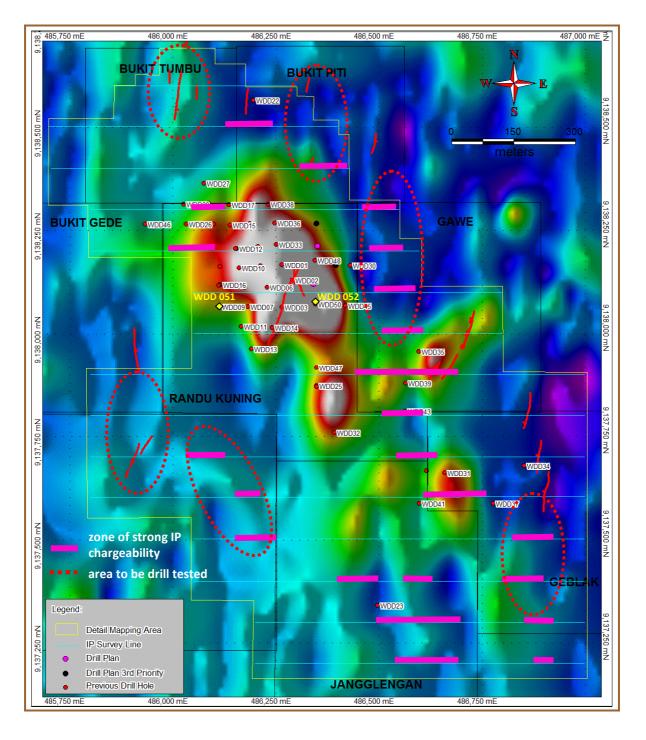

WDD051 drilled down through the previous hole WDD009 and began coring from the bottom of the previous hole (305.6 metres), continuing to a hole depth of 388.2 metres. WDD051 intersected a deeper zone of 4.3 metres of 0.99 g/t Au and 0.06% Cu from 368.7 metres downhole, including a 1.0 metre intersection of 2.78 g/t Au and 0.2% Cu. This may represent the vertical continuity of the deep high-grade intersection from previous PT Oxindo Exploration drilling (DDH002) which intersected 45.0 metres of 1.49 g/t Au and 0.21% Cu from 450.0 metres downhole, including a 13.0 metre interval of 2.34 g/t Au and 0.31% Cu from 482.0 metres downhole.

Higher grade zones ( $\geq 1.0$  g/t Au) are interpreted as structurally-controlled 'feeders' related to zones of hydrothermal breccia and sheared rock which based on surface mapping are interpreted to have a general sub-vertical orientation.

Interpreted geological cross-section along line 9138050N showing occurrence of sub-vertical, structurally-controlled hydrothermal breccias and fault zones. High grades zones (>1.0 g/t Au) occur within and proximal to such structural zones. The conceptual pit outline for the same section is also shown and represents the maximum DCF US\$1,250 per ounce Au pit.

Plan map of the Wonogiri project area with reported drill holes indicated on the Reduced to Pole (RTP) magnetic survey map as the base. Also shown are zones of interpreted high IP chargeability and areas of interest to be drill tested during the current drill program. Surface mapping indicates these zones to contain epithermal type quartz veins (indicated by red lines) and associated alteration.

The ongoing 3,000 metre program is now focused on completing drilling of the epithermal gold vein and alteration targets adjacent to Randu Kuning identified by previous surface exploration and further defined by the recent dipole-dipole IP (induced polarisation) geophysical survey. Several drill holes will also specifically test zones of coincident high-chargeability/high resistivity and interpreted structural features.

Wonogiri project location and major porphyry deposits on the Oligocene-Miocene Arc.

The Wonogiri project is located approximately 30 kilometres to the south of the provincial city of Solo in central Java and is easily accessible by daily flights from the capital Jakarta and a short one hour drive by car on a sealed road.

A total of 18, 026 metres of drilling in 60 diamond drill holes have been completed at the Wonogiri project. Forty four of these (12,462 metres) have been drilled at the Randu Kuning prospect area. Average drill depths were 318.0 metres with hole depth ranging from 157.6 to 855.0 metres. This work has defined a JORC compliant mineral resource of 1.54 million ounces of gold at a 0.2g/t Au Eq cut-off (90.9 Mt at 0.53g/t Au Eq)<sup>3</sup>.

In March 2014 Augur announced the results of a scoping study of the Randu Kuning deposit located. Highlights of the scoping study undertaken by Australian Mine Design and Development Pty Ltd ('AMDAD') (note cautionary statements on the following page) included:

- Randu Kuning deposit generating a life of project positive net cash flow of US\$143M undiscounted, or US\$102M when a 5% discount factor is applied (excluding contingency) for relatively low capital expenditure.
- Open cut mine delivering approximately 9 years of production at 1.74 to 2.00 Mtpa at 0.61 g/t Au and 0.16% Cu.

- Life of mine production of **283,000 ounces of gold** and **236,000 tonnes of copper** in concentrate, or **426,000 ounces gold equivalent** ('AuEq')<sup>1</sup> at an average C1 cash cost<sup>2</sup> of **US\$786** per ounce AuEq using US\$1,250 per ounce Au and US\$7,900 per tonne Cu
- Low preliminary capital expenditure estimate of **US\$56M** (excluding contingency) to build a second hand plant and associated infrastructure costs due to excellent infrastructure and good access.
- Low strip ratio of **1.79** : **1.00**.
- Total current Randu Kuning resource estimate is 90.9 million tonnes at 0.35 g/t
   Au and 0.10% Cu.
- Randu Kuning deposit remains open at depth and to the east, south and west
  with significant opportunity to expand the current resource and test other
  regional targets.

#### **Scoping Study Cautionary Statements**

The Company cautions that production and cash flow estimates presented in the scoping study are indicative only. The following should be considered:

- Although the Randu Kuning Measured and Indicated resource categories exceed
  the scoping study production target, the mill feed schedule includes a proportion
  of Inferred category material which has a low level of geological confidence and
  no certainty that further exploration work will result in the determination of
  Indicated resources or that the production target will be realised.
- The mining loss and dilution estimates have not been assessed in detail against the deposit geometry.
- Pit optimisations and designs use assumed pit wall slopes. No geotechnical analyses have yet been undertaken.
- Process recoveries are extrapolated from limited test work results.
- The available metallurgical test work was done on a small composite with grades well in excess of the likely mill head grades for the project.
- Mining costs have not been developed in detail, although they have been reviewed by Leighton Contractors Indonesia.
- Process operating costs are based on a USA cost database. While adjustments
  have been made for local conditions, AMDAD is a mining engineering
  consultancy and cannot accept responsibility for their accuracy.

For further information, please contact Peter Nightingale on +61 2 9300 3310.

Yours sincerely

Peter Nightingale Director

pjn7728

#### **Statement of Compliance**

The information in this report that relates to Mineral Exploration is based on information compiled by Augur staff and contractors and approved by Mr Michael Corey PGeo., who is a Member of the Association of Professional Geoscientists of Ontario (APGO) in Canada. Michael Corey is a full-time employee of Augur Resources and has sufficient experience which is relevant to the style of mineralisation and type of deposit under consideration and to the activity which he is undertaking to qualify as a Competent Person as defined in the 2012 Edition of the 'Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves'. Michael Corey has consented to the inclusion in this report of the matters based on his information in the form and context in which they appear.

Information regarding the mineral resource was prepared and first disclosed under the 2004 Edition of the 'Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves'. It has not been updated since to comply with the 2012 Edition of the 'Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves' on the basis that the Company is not aware of any new information or data that materially affects the information and, in the case of the resource estimate, all material assumptions and technical parameters underpinning the estimate continue to apply and have not materially changed.

#### <sup>1</sup> Gold Equivalent Calculation relating to the Scoping Study

Where reported in relation to the Wonogiri scoping study, Gold Equivalent results are calculated using a gold price of US\$1,250/oz and a copper price of US\$7,900/t. Silver is excluded from the gold equivalent calculation as no metallurgical testing of the recovery properties of silver from this project has occurred. In calculating Gold Equivalents for the drill results in the table above, gold and copper recoveries are assumed to be 100%. As previously reported, metallurgical testing has resulted in mean recoveries from sulphide material of over 82.5% for gold and 94% for copper. It is the Company's opinion that all metals used in the equivalent calculation have a reasonable potential to be recovered in the event that material from the Wonogiri project was to undergo processing.

The gold equivalent calculation used is AuEq (g/t) = Au (g/t) + ((Cu (%)\*7,900)/40.19). (i.e.: 1.0% Cu = 1.97 g/t Au)

#### <sup>2</sup> C1 cash costs

The costs of mining, milling and concentrating, onsite administration and general expenses, property and production royalties not related to revenues or profits, metal concentrate treatment charges, and freight and marketing costs less the net value of the by-product credits.

#### <sup>3</sup> Gold Equivalent Calculation relating to the Wonogiri Resource

Where reported in relation to the Wonogiri mineral resource estimate, Gold Equivalent results are calculated using a gold price of US\$1,198/oz and a copper price of US\$6,945/t. Silver is excluded from the gold equivalent calculation as no metallurgical testing of the recovery properties of silver from this project has occurred. In calculating Gold Equivalents for the drill results in the table above, gold and copper recoveries are assumed to be 100%. As previously reported, metallurgical testing has resulted in mean recoveries from sulphide material of over 82.5% for gold and 94% for copper. It is the Company's opinion that all metals used in the equivalent calculation have a reasonable potential to be recovered in the event that material from the Wonogiri project was to undergo processing.

The gold equivalent calculation used is AuEq(g/t) = Au(g/t) + ((Cu(%)\*6,945)/38.51). (i.e.: 1.0% Cu = 1.80 g/t Au)

### **ATTACHMENT 1**

# JORC Code, 2012 Edition – Table 1 report SPL1454

### **Section 1 Sampling Techniques and Data**

(Criteria in this section apply to all succeeding sections.)

Criteria	JORC Code explanation	Commentary
Sampling techniques	<ul> <li>Nature and quality of sampling (eg cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</li> <li>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</li> <li>Aspects of the determination of mineralisation that are Material to the Public Report.</li> <li>In cases where 'industry standard' work has been done this would be relatively simple (eg 'reverse circulation drilling was used to obtain 1 m samples from which 3 kg was pulverised to produce a 30 g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (eg submarine nodules) may warrant disclosure of detailed information.</li> </ul>	<ul> <li>Diamond drill core was logged by geologists for major lithological units and alteration zones to determine sampling intervals. All sample intervals were marked by core blocks, entered into a ledger and assigned a unique sample number. After cutting and sampling detailed logging continued using standardized forms which were entered into the database and verified daily. Diamond drill core samples are collected from electric saw cut half core at intervals generally either 1.0 metre or 2.0 metres.</li> <li>At the site office the core boxes were weighed and photographed (wet and dry), logged, and then marked-up for half-core cutting and sampling by trained technicians. All work was directly supervised by the Site Geologist.</li> <li>Samples were oven dried at 105°C, weighed then jaw crushed to 95% &lt;2mm. A 1.5 kg subsample was riffle spit for pulverizing to 95%&lt;200#. Two splits were taken from this product, one for analysis the other for QAQC. Samples were analysed for gold using method FA51, a lead collection fire assay using a 50g charge with an AAS finish. Base metals contents were estimated by method IC01, which used an aqua regia digest with ICP-OES finish.</li> </ul>
Drilling techniques	• Drill type (eg core, reverse circulation, open- hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (eg core diameter, triple or standard tube, depth of diamond tails, face- sampling bit or other type, whether core is oriented and if so, by what method, etc).	Diamond drill including PQ, HQ and NQ core collection utilizing standard triple-tube wire line equipment. Holes are surveyed upon completion using a downhole camera.

Criteria	JORC Code explanation	Commentary
Drill sample recovery	<ul> <li>Method of recording and assessing core and chip sample recoveries and results assessed.</li> <li>Measures taken to maximise sample recovery and ensure representative nature of the samples.</li> <li>Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material.</li> </ul>	<ul> <li>Core was cut in half using an electric powered, water cooled diamond blade core cutter located at the site office. Core samples were cut carefully to minimise breakage and to prevent parts of the sample being washed away during cutting. Core intervals that were clay rich and broken or friable were not cut but representatively sampled by spatula and spoon.</li> <li>Drilling supervisors informed prior to start of hole where intersection expected.</li> <li>Half core was bagged according to the sample specifications. PQ core was generally sampled in 0.5 metre lengths whilst HQ and NQ core was sampled in 1 metre lengths where mineralised and 2 metre lengths elsewhere. Sampling intervals were constrained to major lithologic boundaries.</li> <li>There is no significant relationship between recovery and grade.</li> </ul>
Logging	<ul> <li>Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical studies.</li> <li>Whether logging is qualitative or quantitative in nature. Core (or costean, channel, etc) photography.</li> <li>The total length and percentage of the relevant intersections logged.</li> </ul>	<ul> <li>Diamond drill core was logged by geologists for lithological units and alteration zones and structural features to determine sampling intervals. All sample intervals were marked by core blocks, entered into a ledger and assigned a unique sample number. After cutting and sampling detailed logging continued using standardized forms which were entered into the database and verified daily. Core logging is both qualitative and quantitative. Core is logged descriptively and codes are used to describe alteration type/intensity, quartz type and intensity as well as various percentages of minerals. Structural data including veins, shears, fractures are recorded relative to the core axis.</li> <li>Core recovery and RQD are recorded in the Geotechnical log. The average core recovery from 60 drillholes (metres) is 96%. Recoveries of less than 90% are (depending on the cause of reduced recovery) redrilled to obtain better recovery if necessary. At the site office the core boxes were weighed and photographed (wet and dry), logged, and then marked-up for half-core cutting and sampling by trained technicians. All work was directly supervised by the Site Geologist.</li> </ul>

Criteria	JORC Code explanation	Commentary
Sub-sampling techniques and sample preparation	<ul> <li>If core, whether cut or sawn and whether quarter, half or all core taken.</li> <li>If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry.</li> <li>For all sample types, the nature, quality and appropriateness of the sample preparation technique.</li> </ul>	<ul> <li>Selected core, based on lithology, alteration and visible mineralization was cut in half using an electric powered, water cooled diamond blade core cutter located at the site office. Half core samples are collected at 1m or in some cases 2 metre intervals.</li> <li>Blanks and/or independent standards are used in each sample batch at approximately each 10 sample interval. Standards were</li> </ul>
	<ul> <li>Quality control procedures adopted for all subsampling stages to maximise representivity of samples.</li> <li>Measures taken to ensure that the sampling is representative of the in situ material collected, including for instance results for field duplicate/second-half sampling.</li> <li>Whether sample sizes are appropriate to the grain size of the material being sampled.</li> </ul>	purchased from Ore Research & Exploration Pty Ltd [Bayswater North, Australia]. At the Intertek laboratory samples were oven dried at 105°C, weighed then jaw crushed to 95% <2mm. A 1.5 kg subsample was riffle spit for pulverizing to 95%<200#. Two splits were taken from this product, one for analysis the other for QAQC. Samples were analysed for gold using method FA51, a lead collection fire assay using a 50g charge with an AAS finish. Base metals contents were estimated by method ICO1, which used an aqua regia digest with ICP-OES finish.
Quality of assay data and laboratory tests	<ul> <li>The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total.</li> <li>For geophysical tools, spectrometers, handheld XRF instruments, etc, the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc.</li> <li>Nature of quality control procedures adopted (eg standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (ie lack of bias) and precision have been established.</li> </ul>	<ul> <li>Assaying is completed by PT Intertek Utama Services in Jakarta, a subsidiary of Intertek Group Inc. (accredited for chemical testing under ISO/ICE 17025:2005).</li> <li>A structured Quality-Assurance-Quality-Control program has been conducted during all drill phases. The program has consisted of regular submission of blanks and prepared standards and comparative sample runs with other laboratories. Standards were purchased from Ore Research &amp; Exploration Pty Ltd [Bayswater North, Australia]</li> <li>Assays falling outside of acceptable ranges are re-assayed. Intertek Laboratories also carry out routine internal quality control, and review of this data suggests there are no issues with either precision or accuracy.</li> <li>Separate groups of mineralised sample pulps are sent on a routine basis to other accredited laboratories in Jakarta to test for laboratory scale systematic errors.</li> </ul>

Criteria	JORC Code explanation	Commentary
Verification of sampling and assaying	<ul> <li>The verification of significant intersections by either independent or alternative company personnel.</li> <li>The use of twinned holes.</li> </ul>	<ul> <li>In 2011 the company arranged for renowned consultant Mr Greg Corbett to review the geological /deposit model and also evaluate the assay database and QAQC protocols.</li> </ul>
	<ul> <li>Documentation of primary data, data entry procedures, data verification, data storage (physical and electronic) protocols.</li> <li>Discuss any adjustment to assay data.</li> </ul>	<ul> <li>As the drilling to date has been entirely by diamond drill no twinned holes have been completed. It is expected that some number of twinned holes will be completed as part of the proposed feasibility study.</li> </ul>
	Discuss any adjustment to assay data.	<ul> <li>All field and laboratory data is entered into an Excel database with QA/QC templates included.</li> </ul>
		<ul> <li>No adjustments to the assay data has occurred.</li> </ul>
Location of data points	<ul> <li>Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation.</li> </ul>	<ul> <li>Initially collars are located with hand held GPS devices. Drill collar elevations and hole locations are later recorded with differential GPS equipment by a licenced surveyor.</li> </ul>
	<ul><li> Specification of the grid system used.</li><li> Quality and adequacy of topographic control.</li></ul>	<ul> <li>The mapping grid is WGS 84, Zone 49 South.</li> <li>Topographic control is by Lidar survey and differential GPS.</li> </ul>
Data spacing and distribution	<ul> <li>Data spacing for reporting of Exploration Results.</li> <li>Whether the data spacing and distribution is sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied.</li> <li>Whether sample compositing has been applied.</li> </ul>	• Core samples are generally taken over 1m intervals from surface to the end of hole. Drill holes vary from 50 metres to 100 metres apart. Holes were drilled due East and due West across apparent preferred orientations of mineralization and controlling structural features. Varigraphy and kriging were used to produce a resource block model in support of an initial JORC compliant mineral resource estimate completed by Computer Aided Geoscience Pty Limited and reported by the company in September 2012. Based on drill density and the quality of the exploration database the resource within the modeled gold and copper zones was categorized at Measured or Indicated based on the interpolation parameters used to estimate the block grade. Mineralisation outside of the modelled zones is categorized as Inferred.
		<ul> <li>Some composite samples were made based on Au grades to provide representative material for metallurgical testing. The testwork was completed by ALS Ammtec in Perth and results were reported by the company in May 2012.</li> </ul>

Criteria	JORC Code explanation	Commentary
Orientation of data in relation to geological structure	<ul> <li>Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known, considering the deposit type.</li> <li>If the relationship between the drilling orientation and the orientation of key mineralised structures is considered to have introduced a sampling bias, this should be assessed and reported if material.</li> </ul>	<ul> <li>Holes were drilled to obtain representative mineralised intersections across interpreted structural controlling features. The structures are interpreted to be subvertical and trending generally northeast /northwest/north. As such drillholes were drilled either due East or due West with declinations of -40 -65 degrees.</li> <li>No oriented drill holes have been completed so reported widths are downhole or apparent widths and not true widths.</li> <li>Based on current interpretation the reported widths are likely to be some degree wider than the true widths.</li> </ul>
Sample security	The measures taken to ensure sample security.	<ul> <li>Sample batches were packed into sealed and annotated rice sacks and road transported by the company to the Intertek laboratory in Jakarta. Samples were subjected to full security from drilling through processing till delivery to the laboratory. Intertek standard sample submission forms were cross- checked with Sample Receipt Confirmation notes issued by the Laboratory. Laboratory results were emailed to the site office as well as the corporate offices in Jakarta and Sydney.</li> </ul>
Audits or reviews	<ul> <li>The results of any audits or reviews of sampling techniques and data.</li> </ul>	<ul> <li>The sampling and assay database were audited and validated in 2012 during preparation of the initial mineral resource estimate. The current drilling program is the first to occur since the 2012 resource estimate.</li> </ul>

## **Section 2 Reporting of Exploration Results**

(Criteria listed in the preceding section also apply to this section.)

Criteria	JORC Code explanation	Commentary
Mineral tenement and land tenure status	<ul> <li>Type, reference name/number, location and ownership including agreements or material issues with third parties such as joint ventures, partnerships, overriding royalties, native title interests, historical sites, wilderness or national park and environmental settings.</li> <li>The security of the tenure held at the time of reporting along with any known impediments to obtaining a licence to operate in the area.</li> </ul>	<ul> <li>The 3,928 hectare Wonogiri Property tenure is under the Indonesian National Izin Usaha Pertambangan or Mining Business License (IUP) system. The Wonogiri IUP (545.21/054/2009) is held 100% by PT Alexis Perdana Mineral ('Alexis'). Augur's subsidiary, Wonogiri Pty Ltd, directly holds a 90% interest in Alexis.</li> <li>The IUP is currently in the Exploration Stage and must be converted to an Exploitation license by January 2015.</li> <li>There are no forestry restrictions over the IUP nor any social or environmental issues known.</li> </ul>
Exploration done by other parties	Acknowledgment and appraisal of exploration by other parties.	The Wonogiri property was previously explored by PT Oxindo a wholly-owned subsidiary of MMG Ltd during 2009-2010. Oxindo completed surface mapping, sampling and a ground magnetic survey followed by drilling of 5 holes (1,996.3 metres) to test porphyry Cu-Au targets. Although the drilling confirmed the presence of porphyry-type mineralization within the Randu Kuning prospect area the resource potential was deemed too small. The property was JV to Augur in 2011.
Geology	Deposit type, geological setting and style of mineralisation.	• The Wonogiri property is host to porphyry- type copper-gold mineralization at the Randu Kuning deposit and also associated low sulphidation epithermal type, quartz vein hosted gold mineralization in adjacent prospect areas. The property lies within the tectonically complex Sunda-Banda Magmatic Arc which hosts the world-class Batu Hijau and Tujuh Bukit porphyry copper-gold deposits.

Criteria	JORC Code explanation	Commentary
Drill hole Information	<ul> <li>A summary of all information material to the understanding of the exploration results including a tabulation of the following information for all Material drill holes:         <ul> <li>easting and northing of the drill hole collar</li> <li>elevation or RL (Reduced Level – elevation above sea level in metres) of the drill hole collar</li> <li>dip and azimuth of the hole</li> <li>down hole length and interception depth</li> <li>hole length.</li> </ul> </li> <li>If the exclusion of this information is justified on the basis that the information is not Material and this exclusion does not detract from the understanding of the report, the Competent Person should clearly explain why this is the case.</li> </ul>	<ul> <li>A total of 18, 026 metres of drilling in 60 diamond drill holes have been completed at the Wonogiri project. Forty four of these (12,462 metres) have been drilled at the Randu Kuning prospect area. Average drill depths were 318.0 metres with hole depth ranging from 157.6 to 855.0 metres. This work has defined a JORC compliant mineral resource of 1.54 million ounces of gold at a 0.2g/t Au Eq cut-off (90.9 Mt at 0.53g/t Au Eq).</li> <li>Summaries of all drill holes with pertinent drill hole collar and survey information indicated in this release are included in previous Announcements and Annual Reports released via the ASX.</li> </ul>

Criteria	JORC Code explanation	Commentary
Data aggregation methods	<ul> <li>In reporting Exploration Results, weighting averaging techniques, maximum and/or minimum grade truncations (eg cutting of high grades) and cut-off grades are usually Material and should be stated.</li> <li>Where aggregate intercepts incorporate short lengths of high grade results and longer lengths of low grade results, the procedure used for such aggregation should be stated and some typical examples of such aggregations should be shown in detail.</li> <li>The assumptions used for any reporting of metal equivalent values should be clearly stated.</li> </ul>	<ul> <li>Aggregate (compiled) significant intersections reported are based on assays utilizing a cut-off of 0.2 g/t gold and/or 0.2% copper with a maximum contiguous dilution interval of 4.0 metres. The intervals reported are downhole intervals and reported assays are averages for the interval and unless otherwise stated are not weighted averages. Use of weighted averages were not deemed necessary given that sampled lengths and core sizes were the same. Reported intervals of higher grades (≥1.0 g/t) within a wider lower grade interval are stated using the same parameters and are included in order to denote the tenor of interpreted primary, structurally controlled feeder zones.</li> <li>Where reported, Gold Equivalent (Au Eq) results are calculated using a gold price of US\$6,945/t. Silver is excluded from the gold equivalent calculation as no metallurgical testing of the recovery properties of silver from this project has occurred. In calculating Gold Equivalents for the drill results, gold and copper recoveries are assumed to be 100%. As previously reported, metallurgical testing has resulted in mean recoveries from sulphide material of over 82.5% for gold and 94% for copper. It is the Company's opinion that all metals used in the equivalent calculation have a reasonable potential to be recovered in the event that material from the Wonogiri project was to undergo processing. The gold equivalent calculation used is AuEq (g/t) = Au (g/t) + ((Cu (%)*6,945)/38.51); (i.e.: 1.0% Cu = 1.80 g/t Au)</li> </ul>
Relationship between mineralisatio n widths and intercept lengths	<ul> <li>These relationships are particularly important in the reporting of Exploration Results.</li> <li>If the geometry of the mineralisation with respect to the drill hole angle is known, its nature should be reported.</li> <li>If it is not known and only the down hole lengths are reported, there should be a clear statement to this effect (eg 'down hole length, true width not known').</li> </ul>	<ul> <li>No oriented drill holes have been completed so reported widths are downhole or apparent widths and not true widths.</li> <li>Based on current interpretation the reported widths are likely to be some degree wider than the true widths.</li> </ul>

Criteria	JORC Code explanation	Commentary
Diagrams	<ul> <li>Appropriate maps and sections (with scales) and tabulations of intercepts should be included for any significant discovery being reported These should include, but not be limited to a plan view of drill hole collar locations and appropriate sectional views.</li> </ul>	Pertinent maps and sections are included
Balanced reporting	<ul> <li>Where comprehensive reporting of all Exploration Results is not practicable, representative reporting of both low and high grades and/or widths should be practiced to avoid misleading reporting of Exploration Results.</li> </ul>	Reporting is fully representative of the data.
Other substantive exploration data	Other exploration data, if meaningful and material, should be reported including (but not limited to): geological observations; geophysical survey results; geochemical survey results; bulk samples – size and method of treatment; metallurgical test results; bulk density, groundwater, geotechnical and rock characteristics; potential deleterious or contaminating substances.	All data is fully reported.
Further work	<ul> <li>The nature and scale of planned further work (eg tests for lateral extensions or depth extensions or large-scale step-out drilling).</li> <li>Diagrams clearly highlighting the areas of possible extensions, including the main geological interpretations and future drilling areas, provided this information is not commercially sensitive.</li> </ul>	The results reported are from the first 2 holes of a planned 3,000 drill program.     Drilling is currently tested epithermal veins targets immediately adjacent to the Randu Kuning deposit area.

Section 3 does not apply as the information regarding the mineral resource was prepared and first disclosed under the 2004 Edition of the 'Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves'. It has not been updated since to comply with the 2012 Edition of the 'Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves' on the basis that the Company is not aware of any new information or data that materially affects the information and, in the case of the resource estimate, all material assumptions and technical parameters underpinning the estimate continue to apply and have not materially changed. Section 4 does not apply as reserve estimates are not being disclosed at this time and Section 5 does not apply as this section relates to the reporting of diamonds and other gemstones.
