

CONFIRMATION OF NICKEL-COPPER-PGM POTENTIAL *100% owned Ampanihy Project – Southern Madagascar*

HIGHLIGHTS

- Systematic regional geochemical sampling and programs of mapping have identified an extensive suite of mafic-ultramafic intrusive rocks associated with the regionally significant Ampanihy Suture Zone in the southern Maniry Area;
- Extensive zones of coincident nickel-copper soil geochemistry associated with a number of the intrusions have been defined;
- Rock chip results from gossanous material in outcropping positions have returned results consistent with the presence of sulphides containing nickel-copper-platinum group metals. Results include:
 - Sample MD9306: **3722ppm Ni, 1666ppm Cu, 156ppb Pt-Pd**
 - Sample MD9303: **3650ppm Ni, 308ppm Cu, 260ppb Pt-Pd**
 - Sample MD9286: **1606ppm Ni, 469ppm Cu, 75ppb Pt-Pd**
 - Sample MD9287: **1184ppm Ni, 661ppm Cu, 125ppb Pt-Pd**

BACKGROUND

Malagasy Minerals Limited (ASX Code: MGY / “Malagasy”) has established a large exploration project in Southern Madagascar that is prospective for both mafic-ultramafic intrusive related nickel-copper-platinum group metals (PGM) deposits and high-grade high-quality graphite deposits (Figure 1). This is being undertaken both on a 100% basis and through joint venture.

The Ampanihy Project has been confirmed as a host for a significant suite of mafic-ultramafic intrusive rocks that have demonstrated potential to host nickel-copper-PGM mineralisation. Having established that the application of systematic regional geochemical sampling and programs of mapping and rock chip sampling is the most effective way of exploring the entire 110km strike of the project a work program involving the collection of approximately 4,000 soil samples has been completed across the entire project. 50% of these samples covering the southern half of the project have now been analysed: the results of which have confirmed the potential of the project to host a significant mafic-ultramafic intrusive related Ni-Cu-PGM deposit.

NICKEL-COPPER-PGM EXPLORATION RESULTS

Exploration for Ni-Cu-PGM has been focused along a major documented structural zone referred to as the “*Ampanihy Suture Zone*”. This feature has been the focus of a substantial intrusive event that has seen a suite of intrusive rocks ranging from anorthosite, through gabbro to ultramafic peridotite and dunite. These intrusive rocks are now referred to as the “*Ampanihy Plutonic Suite*”. This geological setting is interpreted to be analogous to that described at Voisey’s Bay.

Key results of the recent exploration initiative include:

- Identification of 4 clusters of mafic-ultramafic intrusive rocks in close proximity to the Ampanihy Suture Zone. Individual intrusions are up to ~5km long but are more typically ~2km long (Figure 2);
- Strong coincident Ni-Cu geochemical anomalies associated with a number of the intrusions; and

- Identification of a zone of outcropping strongly gossanous material (semi-oxidised to oxidized rock) that has returned highly anomalous nickel, copper, platinum, palladium and sulphur results from rock chip samples from “Target C” (Figure 3).

Table 1: Results of Rock Chip Samples

Sample No	Nickel (ppm)	Copper (ppm)	Platinum (ppb)	Paladium (ppb)	Sulphur (ppm)
MD9306	3722	1666	129	27	5430
MD9303	3650	308	44	216	1757
MD9286	1606	469	39	36	3537
MD9287	1184	661	68	57	11794

Note:

Assaying of rock chips was undertaken by Intertek-Genalysis in Perth. Samples were pulverized, representatively sampled, digested by 4 acids and then analyzed by mass spectrometer for 53 elements including PGE's. Internal laboratory QAQC procedures were adhered to with results later checked by the MGY Senior Geologist.

XRF analysis of the soil samples was undertaken with a handheld Innov-X Delta Premium XRF unit. The machine was routinely calibrated and CRM material inserted into sample runs for QAQC purposes. Reading time varied for different batches of samples between 30 seconds or 90 seconds (3 beams). Data was routinely checked with internal QAQC standards met.

See Appendix (2) for JORC Code 2012 Edition commentary on Sampling Techniques and Data

See Appendix (1) for full details.

Given the tenor of the results, and including the levels of sulphur, it is likely that the results are related to the presence of nickel-copper-PGM sulphides. Petrographic analysis is currently underway to confirm this.

These results have now identified an advanced high priority target. The “Target C” mafic ultramafic intrusion represents a ~2km long by ~0.5-0.8km wide mafic-ultramafic intrusion that has a strong coincident Ni-Cu anomaly surrounding it and an identified zone of gossanous material that is highly anomalous in Ni-Cu-Pt-Pd-S; likely to be related to sulphide mineralisation.

These results clearly demonstrate that a highly prospective suite of mafic-ultramafic intrusive rocks has been identified in the southern half of Malagasy Mineral Ampanihy Project and that the application of low-cost, high-value exploration techniques has been effective.

FUTURE WORK

- The remainder of the soil and rock chip samples that were collected over the northern part of property are currently being analysed using a portable XRF. High tenor results will then be re-submitted for laboratory analysis. Results of this work will be reported as they come to hand;
- Petrographic analysis of samples to identify sulphides;
- Following the end of the wet season (March) an initial program of detailed mapping and sampling of each of the defined target areas will be undertaken; and
- Based on results geophysical programs of airborne magnetics and ground based electromagnetic will be considered.

For and on behalf of the Board

***Peter Langworthy
Technical Director***

Competent Persons Statement

The information in this report that relates to Exploration Results or Mineral Resources is based on information compiled or reviewed by Mr. Peter Langworthy, Consulting Geologist, who is a Member of the Australian Institute of Mining and Metallurgy. Mr. Peter Langworthy is a full time Director of Malagasy Minerals Limited and has sufficient experience, which is relevant to the style of mineralisation and types of deposit under consideration and to the activities undertaken, to qualify as a Competent Person as defined in the 2012 Edition of the "Australasian Code of Reporting of Exploration Results, Mineral Resources and Ore Reserves". Mr. Peter Langworthy consents to the inclusion in the report of the matters based on the information in the form and context in which it appears.

JORC Code, 2012 Edition – Table 1 report template

Section 1 Sampling Techniques and Data

(Criteria in this section apply to all succeeding sections.)

Criteria	JORC Code explanation	Commentary
Sampling techniques	<ul style="list-style-type: none"> Nature and quality of sampling (eg cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling. Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used. Aspects of the determination of mineralisation that are Material to the Public Report. In cases where 'industry standard' work has been done this would be relatively simple (eg 'reverse circulation drilling was used to obtain 1 m samples from which 3 kg was pulverised to produce a 30 g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (eg submarine nodules) may warrant disclosure of detailed information. 	<ul style="list-style-type: none"> Soil samples – 4110 collected – were taken on a pre-designated grid with GPS used to locate the sample location. A representative piece of ground was chosen in the vicinity of the location with any loose debris and vegetation removed. The top 5cm of 'topsoil' was removed from an area measuring 50 x 50cm with a further pit dug within with the resultant soil suitably homogenized. Soil was then sieved to 177µm (#80 mesh) with approximately 120g of sample collected in a paper bag and stored appropriately. Rock chips – 204 collected - were taken from locations identified as prospective by the field geologist. Approximately 2.5kg of sample was taken and placed in a calico bag. Samples may have been from one single point or from a number of points within a 5-10m radius An Innov-X Delta Premium XRF analyzer was used to analyze all soil samples whilst rock chips were assayed at a laboratory.
Sub-sampling techniques and sample preparation	<ul style="list-style-type: none"> If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry. For all sample types, the nature, quality and appropriateness of the sample preparation technique. Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples. Measures taken to ensure that the sampling is representative of the in situ material collected, including for instance results for field duplicate/second-half sampling. Whether sample sizes are appropriate to the grain size of the material being sampled. 	<ul style="list-style-type: none"> All samples were dry at point of collection Field QC procedures for all soil and rock chip sampling programs involve the use of Certified Reference Material (CRM) as assay standards and field duplicate samples at a frequency of 1 in every 30 samples. All QA/QC controls and measures are routinely reviewed and reported on at the completion of the program. External laboratory QA/QC checks are routinely monitored and stored in the MGY database. Sample size is considered adequate for the rocks encountered, mineralization style and purpose of this program.
Quality of assay data and laboratory tests	<ul style="list-style-type: none"> The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total. For geophysical tools, spectrometers, handheld XRF instruments, etc, the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc. 	<ul style="list-style-type: none"> Assaying of rock chips was undertaken by Intertek-Genalysis in Perth. Samples were pulverized, representatively sampled, digested by 4 acids and then analyzed by mass spectrometer for 53 elements including PGE's. Internal laboratory QAQC procedures were adhered to with results later checked by the MGY Senior Geologist. XRF analysis of the soil samples was
