HIGHLIGHTS

- **Total JORC 2012 resources in Dubbo alone doubles to 312,800oz gold equivalent at 21.98g/t;**
- **Updated resource estimate place Talisman among the highest grade underground gold mines globally;**
- **Updated Pre-feasibility study the next step in the development of Talisman Deeps;**
- **Resource upgrades of remaining Talisman Deeps modules by 31 July;**
- **Development work underground has commenced;**
- **Acceleration and/or expansion of exploration & extraction programmes to be considered;**
- **NTL Fully funded to 2020 under current prospecting and bulk sampling plans.**

New Talisman Gold Mines Ltd (ASX:NTL, NZX:NTL) today announced a substantial upgrade to its gold resources after the completion of the first module pertaining to the Talisman Deeps project in the Coromandel region of New Zealand.

Resource modelling of the Dubbo Zone has resulted in Measured, Indicated, and Inferred resources increasing to 312,800 oz gold equivalent (Au Eq) at a grade of 21.98g/t Au Eq. This is an increase of 102% over the 2004 resource estimate of 140,600 oz gold and 445,800 oz Ag for this zone (154,690 oz Au Eq). Reporting standards are compliant with those set out in the 2012 version of the JORC Code.

Matthew Hill said – The grades established of up to 146.2g/t for an average of 21.98g/t places this deposit as one of the highest grade mineral resources in NZ and ranks in the top 5 worldwide. The dramatic increase in Dubbo resources ultimately proves our long-held belief that there is significant remaining ore at depth. The data compilation and resource modelling has brought a much greater understanding of the mine and sets a very positive platform for long term mine development at Talisman. Work at site continues to progress underground and is on budget and ahead in project timelines.

Figure 1 - Work in progress with support upgrades at the Talisman Project

Mineral resources upgrades to JORC 2012 standards are underway at three other modules within the Talisman Deeps zone:- they lie under the Talisman workings that currently are being refurbished by the company. Bulk sampling of the Mystery Vein zone will be undertaken once that refurbishment is completed.

The increase in measured, indicated, and inferred gold equivalent resources in the Dubbo Zone is a significant milestone and demonstrates the potential for increasing the life of the project.

Source: Natural Resources Ltd, 2013

A further 95,000 oz Au Eq has also been identified at a grade of 23.75g/t as exploration potential, giving a total Mineral Inventory for the Dubbo Zone of 408,000 oz Au Eq.

The exploration potential constitutes a global Exploration Target as defined in the 2012 JORC Code. The potential quantity and grade is conceptual in nature and there has been insufficient exploration to estimate a Mineral Resource. It is uncertain if further exploration will result in the estimation of a Mineral Resource

New Talisman removed a stockpile of remnant ore believed to be representative of ore from the Dubbo zone in 2014. It was milled at Newmont's Waihi treatment facility and returned on average 42g/t gold.

The prospecting phase, currently well underway at the Talisman site, has established the site and the refurbishment of underground areas is providing access to the Mystery Vein.

Once underground refurbishment and prospecting is completed, the company will initiate a bulk sampling project. Consent from Hauraki District Council has been received to remove 20,000 cubic metres per annum for a period of two years.

The resource upgrade at Dubbo Deeps, together with any further resource increases at Talisman Deeps in its entirety, will be included in an updated pre-feasibility study and ore reserve statement in due course. Where possible, areas identified will be prospected and tested for inclusion into the body of works during Bulk Sampling.

Based on current plans the company is fully funded for completion of the Talisman Deeps resource modelling and completion of prospecting and Bulk sampling through to 2020. The Board will consider acceleration and/or expansion of exploration and extraction plans subject to funding.

Figure 2 - Oblique view of the Maria Vein wireframe with historic drives shown in grey, the Dubbo Zone is shown in red. This is the pre-mined model, historic depletions were subtracted from this model.

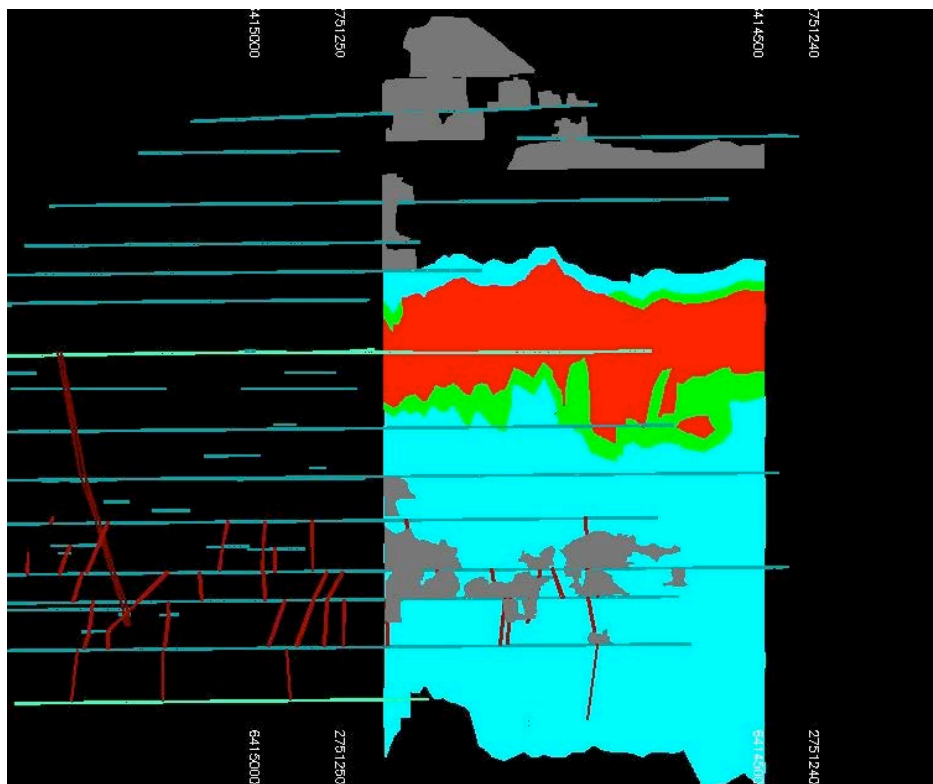

Figure 3 - Long Section showing the Measured (red), Indicated (green) and Inferred Resource blocks with the historic stope shown in grey

The updated resource table for the Dubbo Zone is shown below:

MINERAL RESOURCES- DUBBO ZONE					
CATEGORY	VOLUME	TONNES	AU_EQ G/T	GRAMS	OUNCES
Measured	5,164	13,065	96.91	1,266,175	40,708
Indicated	1,227	3,104	74.87	232,413	7,472
Inferred	144,981	366,802	18.87	6,920,406	264,648
Total Resources	151,372	382,971	21.98	8,418,994	312,829
Exploration Potential	49,322	124,785	23.75	2,963,819	95,289
Inventory In Situ	200,694	507,756	22.42	11,382,813	408,118

Table 1: Dubbo Resources and Potential reported in compliance with the reporting standards set out in the 2012 version of the JORC code.

Figure 4 - Sample taken from Talisman Deeps areas - currently stored at Auckland museum

A lower cut-off grade of 3.0g/t Au Eq (previously 0g/t) was applied to reflect the mine cut-off grade estimated for the financial modelling in the 2013 prefeasibility study. No top cut to the data was applied.

Gold equivalents have been used due as the historic data is expressed in bullion values. These have been converted to gold equivalents based on the gold price during the main historic mining period to 1919 where gold price was a constant £4.25 or USD20.47. All more recent exploration data has been converted to gold equivalents at the same metal prices for consistency of resource estimation and reporting.

WOODSTOCK AND BONANZA/TALISMAN RESOURCES MODULES NEAR COMPLETION

The Company is currently completing the modelling of the Talisman-Bonanza and Woodstock sections of the historic mine where the historic databases acquired in 2015 have shown potential to increase the current resources to JORC 2012 compliance in these sections as well, which would further enhance the overall mineral inventory.

All results will be restated under the JORC 2012 code and modelling will utilise historic channel samples as well as recent exploration data. Locating drill hole data from holes drilled from 15 Level in 1908 has led to increased confidence to extend the geological interpretation of the Maria Vein to around 300m below sea level and is expected to increase mineral potential further.

It is important to note that the Talisman and Bonanza Zones have not been included in previous resource estimates. However, evaluation of the historic channel sampling and considering recorded production and stope volumes there are a number of areas where there are unmined blocks of potentially economic grades remaining. NTL's engineering team is currently evaluating the ability to access these areas during prospecting and bulk sampling.

The entire Talisman Deeps project including all known data is expected to be finalised by 31 July.

Replacing the JORC 2004 Dubbo Resource with the new estimate for Dubbo and converting the remaining JORC 2004 resources from Woodstock, Crown/Welcome and Mystery to gold equivalents gives total measured, indicated, and inferred resources of 388,000 oz Au_Eq prior to the resource modelling underway on the Woodstock, Bonanza and Talisman areas

For further information please contact:

CEO Matthew Hill on +64 217 95559 or matt@newtalisman.co.nz

METHODOLOGY

The process of estimating the resources in the Talisman Deeps project revolved around incorporating NTL's extensive data from the upper levels of the Talisman Mine with the historic database and historic mine plans acquired in 2015.

This involved;

Scanning historic maps and digitising the old levels, stoped, (mined areas), quartz veins and faults to create a 3D model using several software packages but mainly Datamine Studio EM.

A series of cross sections at 10m to 20m intervals along 1300m of the Maria Vein were constructed from the vein positions mapped on the 16 Levels of the old mine. These were used to create a 3D solid model known as a wireframe. Into this model all the geochemical data was imported into its correct position in space with a majority of the gold mineralised portions lying within the wireframe.

These data were then evaluated within the wireframe model using a variety of geostatistical processes to develop a resource model showing the distribution, grade, and tonnages of mineralisation through the deposit.

Initially, there were concerns around the historic data which comprised several thousand channel samples taken in the early 20th century from the deep levels of the mine. The quality control and assurance procedures in place at the time that the samples were taken could not be directly verified, however, as the data sets were evaluated, it was noted that several of the maps from where the original data were derived were signed by the then mine manager. In addition, samples collected donated to the Auckland Museum came to the Company's attention. These were from the 11, 13 and 14 Levels of the Bonanza and Talisman Zones. These samples had gold and silver grades with them and were presented to the Museum by the Talisman Mine Superintendent. The character of the veins is similar to that observed by the Company in the high grade BM37 zone where electrum, (natural gold:silver alloy) is clearly visible and the grades are consistent with the values recorded in the historic channel samples.

The data spacing for this sampling ranges from less than a metre to around 1.5m and if QAQC in today's terms was available would almost certainly qualify as measured resources under the JORC 2012 Code. Moreover, there are historical production figures that are consistent with the grades in the sampling and the stopes from where the production occurred.

Therefore, on the balance of probabilities, the samples are considered valid and it was decided to model the resource here predominantly at inferred status under JORC 2012 until such time that the Company can sample the areas.

Full details of the methodology and approach taken to the resource modelling can be found in the accompanying Table 1 to this release.

Competent Persons Statement

The information in this report that relates to exploration results, exploration targets and mineral resources is based on information compiled by or supervised by Mr Murray Stevens and Mr Wayne Chowles. Mr Stevens is a consulting geologist and director of New Talisman Gold Mines Ltd, who is a corporate member of the AusIMM. Mr Stevens has sufficient experience which is relevant to the style of mineralisation and type of deposit under consideration and to the activity being undertaken to qualify as a Competent Person as defined in the 2012 Edition of the "Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves".

Mr Chowles is a Mining Engineer and member of the AusIMM. Mr Chowles is a full-time employee of New Talisman Gold Mines Limited, he has sufficient experience which is relevant to the style of mineralisation and type of deposit under consideration and to the activity being undertaken to qualify as a Competent Person as defined in the 2012 Edition of the "Australasian Code for Reporting of Exploration Results, Mineral Resources and Ore Reserves".

Both Mr Chowles and Mr Stevens consent to the inclusion in this report of the matters based on his information in the form and context in which it appears.

About New Talisman Gold Mines Ltd

New Talisman Gold is a dual listed (NZSX & ASX: NTL) with over 1900 shareholders who are mainly from Australia and New Zealand. It is a leading New Zealand minerals development and exploration company with a mining permit encompassing the Talisman mine, one of New Zealand's historically most productive gold mines. Its gold properties near Paeroa in the Hauraki District of New Zealand are a granted mining permit, including a JORC compliant mineral resource and a JORC compliant reserve statement within the original Talisman underground mine, and a binding Agreement for Newcrest Mining to spend up to \$5M on an adjacent exploration permit along strike from the mine, Rahu. The company is now advancing its plans to develop the mine, and advance the exploration project.

JORC Code, 2012 Edition – Table 1

Section 1 Sampling Techniques and Data

(Criteria in this section apply to all succeeding sections.)

Criteria	JORC Code explanation	Commentary
Sampling techniques	<ul style="list-style-type: none"> <i>Nature and quality of sampling (eg cut channels, random chips, or specific specialised industry standard measurement tools appropriate to the minerals under investigation, such as down hole gamma sondes, or handheld XRF instruments, etc). These examples should not be taken as limiting the broad meaning of sampling.</i> <i>Include reference to measures taken to ensure sample representivity and the appropriate calibration of any measurement tools or systems used.</i> <i>Aspects of the determination of mineralisation that are Material to the Public Report.</i> <i>In cases where 'industry standard' work has been done this would be relatively simple (eg 'reverse circulation drilling was used to obtain 1 m samples from which 3 kg was pulverised to produce a 30 g charge for fire assay'). In other cases more explanation may be required, such as where there is coarse gold that has inherent sampling problems. Unusual commodities or mineralisation types (eg submarine nodules) may warrant disclosure of detailed information.</i> 	<ul style="list-style-type: none"> Channel sampling of Levels 7, 7A, 8 and Woodstock of the Talisman Mine and 5A level of the Crown Mine was undertaken using handheld diamond saws. Channel samples were taken at a nominal 5m spacing along strike of veins where exposed. Sample widths across veins were determined by the geology of the vein width. Where vein width is less than 1 metre samples restricted actual vein width. Where greater than a metre sample widths generally are 1 metre and no more than 1.4 metre sample width. Channels were cut to nominal dimensions of 5cm by 10cm to resemble half HQ diamond drill core to provide similar sample support for resource estimation purposes. Sample size was generally 5kg and collected in bins by chipping out each sample with a small pneumatic drill and by hand with cold chisels. The bins were cleaned between each sample to reduce chance of contamination. To ensure representivity, care was taken to ensure equal-mass extraction along the entire channel. Diamond core sampling, based on determination of mineralization from logging, all core halved using diamond saw, mineralized intervals sampled on nominal 1m lengths or to geological boundaries. Remainder of non mineralised material sampled on 2m intervals.
Drilling	<ul style="list-style-type: none"> <i>Drill type (eg core, reverse circulation, open-hole hammer, rotary air blast, auger, Bangka, sonic, etc) and details (eg core diameter, triple</i> 	<ul style="list-style-type: none"> Underground Longyear LM55 electric wireline rig used with a LM75

Criteria	JORC Code explanation	Commentary
techniques	<i>or standard tube, depth of diamond tails, face-sampling bit or other type, whether core is oriented and if so, by what method, etc).</i>	<p>power pack.</p> <ul style="list-style-type: none"> Diamond core all HQT to target depths. In rare instances where ground conditions dictated the drill diameter was reduced to NQ and core size was NQT. All core was oriented using plasticine and holes surveyed with Eastman multi or single shot cameras every 25m and at end of hole. Some 5 holes were drilled using a small conventional Kempe rig in the Woodstock section. Core size was LTK60 core which is larger than NQT core and slightly less than HQT drill core.
Drill sample recovery	<ul style="list-style-type: none"> <i>Method of recording and assessing core and chip sample recoveries and results assessed.</i> <i>Measures taken to maximise sample recovery and ensure representative nature of the samples.</i> <i>Whether a relationship exists between sample recovery and grade and whether sample bias may have occurred due to preferential loss/gain of fine/coarse material.</i> 	<ul style="list-style-type: none"> Diamond core was measured by drillers on site on a run by run basis and again by site geologist who recorded run length, measured core recovered and calculated recovery. These data then entered into spreadsheets and the drill database. Use of triple tube coring maximizes core recovery and ensures maximizing core integrity. In the case of the conventional core from the Kempe rig, core was carefully extracted from the core barrel to maximize core integrity. No known sample bias is likely to have occurred using the sample techniques employed. Core recovery for the Kempe rig holes averages 92.8% (55.55m total metres). Core recovery for the 18 wireline holes averages 96.43% (1058.55m total metres).
Logging	<ul style="list-style-type: none"> <i>Whether core and chip samples have been geologically and geotechnically logged to a level of detail to support appropriate Mineral Resource estimation, mining studies and metallurgical</i> 	<ul style="list-style-type: none"> A comprehensive system of logging procedures were used to a level of detail to support appropriate Mineral Resource estimation. Core logging follows detailed regime of geological logging, noting

Criteria	JORC Code explanation	Commentary
	<p><i>studies.</i></p> <ul style="list-style-type: none"> <i>Whether logging is qualitative or quantitative in nature. Core (or costean, channel, etc) photography.</i> <i>The total length and percentage of the relevant intersections logged.</i> 	<p>core orientations of structures, lithology, mineralization, structure, core photography, geotechnical logging undertaken by experienced field geologists and senior geologists.</p> <ul style="list-style-type: none"> All data were entered into spreadsheets using laptops producing descriptive and graphic logs. All ~1,100m of core was logged.
Sub-sampling techniques and sample preparation	<ul style="list-style-type: none"> <i>If core, whether cut or sawn and whether quarter, half or all core taken.</i> <i>If non-core, whether riffled, tube sampled, rotary split, etc and whether sampled wet or dry.</i> <i>For all sample types, the nature, quality and appropriateness of the sample preparation technique.</i> <i>Quality control procedures adopted for all sub-sampling stages to maximise representivity of samples.</i> <i>Measures taken to ensure that the sampling is representative of the in situ material collected, including for instance results for field duplicate/second-half sampling.</i> <i>Whether sample sizes are appropriate to the grain size of the material being sampled.</i> 	<ul style="list-style-type: none"> Core was sawn in half, with one half taken for sampling, one half retained for reference logging, petrology, check logging, check sampling, metallurgy, geotechnical studies. Representivity of sub-sampling was ensured by using a set of QA measures recommended by independent consultants RSG Global who reviewed the procedures. Quality control included field duplicates,(split from first coarse crush) which were taken every alternate 10th sample, and a preparation duplicate, (split from fine grind) taken every alternate 10th sample. Results show good correlation between core duplicates/originals and coarse crush duplicates/originals. HQ half core is considered to provide a suitable sample support for mineral resource estimation purposes for the type of material. No heterogeneity studies were carried out to investigate the optimal sample size. Underground channel samples were sub-sampled and prepared in the laboratory via industry standard methods (crushing using jaw/Boyd, followed by pulverizing to 75 microns in LM2/5).
Quality of assay data and laboratory	<ul style="list-style-type: none"> <i>The nature, quality and appropriateness of the assaying and laboratory procedures used and whether the technique is considered partial or total.</i> <i>For geophysical tools, spectrometers, handheld XRF instruments, etc,</i> 	<ul style="list-style-type: none"> All assays including the drill data used from past explorers were carried out by certified assay laboratories. NTL used SGS in Waihi, using their standard sample preparation and analytical procedures and internal quality control procedures. All gold assays used a 50g

Criteria	JORC Code explanation	Commentary
tests	<p><i>the parameters used in determining the analysis including instrument make and model, reading times, calibrations factors applied and their derivation, etc.</i></p> <ul style="list-style-type: none"> <i>Nature of quality control procedures adopted (eg standards, blanks, duplicates, external laboratory checks) and whether acceptable levels of accuracy (ie lack of bias) and precision have been established.</i> 	<p>charge fire assay with AAS finish and a detection limit of 0.01ppm. This is a total assay technique and considered appropriate.</p> <ul style="list-style-type: none"> The quality control procedures used include the following: <ul style="list-style-type: none"> Blanks of barren material were introduced every 30 samples, and certified reference materials, obtained from RockLabs were inserted every 10th sample. These showed that there were no issues (e.g. no contamination, and no statistically relevant bias between the certified mean of the CRMs and the laboratory mean of assays for those CRMs) Approximately 10% of the samples from mineralized intervals were sent as umpire samples to Amdel Laboratories at the Macraes site in Central Otago for check sampling against the original SGS samples. These showed that there were no issues (e.g. no statistically relevant bias between the two sets of results) No QC was included for historic sample results from the raise sampling programmes of the early 20th century, which are recorded as value in pounds, shillings and pence and plotted on mine plans signed by the mine manager of the day. Not possible to know what validation process was used on historic data. However, plans are signed by the mine manager of the day. These samples are from the zones modelled and recorded on the mine plans Grades are consistent with those indicated in the Museum samples that are recorded by the then mine superintendent Mr Stanfield of the Talisman Gold Mining Company Ltd.
Verification of sampling and assaying	<ul style="list-style-type: none"> <i>The verification of significant intersections by either independent or alternative company personnel.</i> <i>The use of twinned holes.</i> 	<ul style="list-style-type: none"> Initially, significant intervals were calculated manually but subsequently checked and revised using the compositing functions in CAE software product Down Hole Explorer and also within Datamine Studio EM software. This has been carried out by company personnel

Criteria	JORC Code explanation	Commentary
	<ul style="list-style-type: none"> <i>Documentation of primary data, data entry procedures, data verification, data storage (physical and electronic) protocols.</i> <i>Discuss any adjustment to assay data.</i> 	<p>and independently.</p> <ul style="list-style-type: none"> With regard to the historic samples it is not possible to know what validation process was used at the time. However, plans are signed by the mine manager of the day. In addition, a series of samples from the deep levels of the Bonanza Zone are located in Auckland Museum. These samples are from the zones modelled and recorded on the mine plans. The historic channel samples all have sample widths recorded indicating they were collected as proper channel samples in a systematic manner. Grades are consistent with those indicated in the Museum samples that are recorded by the then mine superintendent Mr Stanfield of the Talisman Gold Mining Company Ltd. Moreover, the recorded production from those levels and the tonnages recorded are broadly consistent with the depletions modelled from NTL's assessment of the mined stopes. NTL have taken a conservative approach; while the data density of the historic sampling would be sufficient to allow classification as Measured Resources NTL have elected to classify them in the Inferred category.
Location of data points	<ul style="list-style-type: none"> <i>Accuracy and quality of surveys used to locate drill holes (collar and down-hole surveys), trenches, mine workings and other locations used in Mineral Resource estimation.</i> <i>Specification of the grid system used.</i> <i>Quality and adequacy of topographic control.</i> 	<ul style="list-style-type: none"> A levelling exercise was initially conducted in 8 Level for survey control with a datum established outside No8 Level. All samples were surveyed to ensure proper XYZ control for modelling purposes. All channel samples were surveyed using peg ledgers and offsets. Each sample recorded collar position, sample length and orientation to create drill hole data. These data are expected to be accurate to

Criteria	JORC Code explanation	Commentary
		<p>cm resolution.</p> <ul style="list-style-type: none"> Each drill hole collar was surveyed and downhole surveys recorded at 25m intervals using Eastman single or multi-shot cameras. A full mine survey using a registered mine surveyor was completed and all sample point surveys adjusted accordingly on the basis of this survey. Historic samples that have been used in the resource estimate were captured from scanned historic mine plans and checked against existing databases. These were then georeferenced to match the geological model wireframe. In most cases collar positions were within 1 to 2 metres of the wireframe and were adjusted accordingly. Grid system used historically was Mt Eden Circuit. NTL used NZMG(1949) and converted all earlier data to this grid system. Topographic and survey control is considered adequate for the purpose that the data is being used.
Data spacing and distribution	<ul style="list-style-type: none"> <i>Data spacing for reporting of Exploration Results.</i> <i>Whether the data spacing and distribution is sufficient to establish the degree of geological and grade continuity appropriate for the Mineral Resource and Ore Reserve estimation procedure(s) and classifications applied.</i> <i>Whether sample compositing has been applied.</i> 	<ul style="list-style-type: none"> Channel samples were generally taken across the backs of exposed veins where available at 5m intervals. The spacing was determined by comparing earlier data taken by the previous mine owners at 2.5m intervals along strike. It was found that the 5m spacing was adequate and gave comparable results. Where there was no exposure in the roof cut, channels were taken along the side walls where oblique veins crossed the drives. Where possible both sides of the drives were sampled to give a 5m separation. A 25m grid drill pattern was designed in the Dubbo zone where NTL drilled the majority of its holes. The pattern was designed to extend beyond known assay data points in earlier drill holes and channel samples and to infill where appropriate to get the required density of

Criteria	JORC Code explanation	Commentary
		<p>data for resource estimation.</p> <ul style="list-style-type: none"> The 2263 historic channel samples are generally close spaced ranging from less than a metre to around 1.5m apart. They are mostly taken up raises with raises generally around 40 to 80m apart. In the Dubbo Zone 767 historic channels range from 0.15m to 3.65m and average 1.03m wide. In the Talisman and Bonanza Zone 1374 historic channels range from 0.15m to 3.65m and average 1.14m wide. In the Woodstock Zone 122 historic channels range from 0.15m to 2.44m and average 1.29m wide as single value assay intervals averaging just over a metre and compositing was not deemed appropriate.
Orientation of data in relation to geological structure	<ul style="list-style-type: none"> <i>Whether the orientation of sampling achieves unbiased sampling of possible structures and the extent to which this is known, considering the deposit type.</i> <i>If the relationship between the drilling orientation and the orientation of key mineralised structures is considered to have introduced a sampling bias, this should be assessed and reported if material.</i> 	<ul style="list-style-type: none"> The Maria Vein trends north to northeast over its strike length and dips to the west ranging from 45 to 85 degrees. NTL channel samples where possible are oriented to be orthogonal to the strike of the vein being sampled. Where this is not possible the channels orientation is reflected in the survey information and is taken into account in the modelling software. Drill holes were designed to intersect mineralised structures orthogonal to strike and dip where possible. In some instances, access issues meant that holes had to be drilled from the hanging wall side and hence some intersections were oblique but again this is accounted for by the software to reflect true width. Historic channel sample data had no survey information other than collar coordinates and channel sample length. The Competent Persons take the view that standard mine sampling practice in the early 20th century was well-developed for grade control sampling and would have been taken across the backs of the veins from hanging

Criteria	JORC Code explanation	Commentary
		<p>wall to footwall at right angles to strike and dip. Hence, historic samples are oriented in the databases at an azimuth of 095° and a dip of -20° reflecting the orientation of the main structures.</p> <ul style="list-style-type: none"> • Sampling bias based on the knowledge of the structure is considered unlikely.
Sample security	<ul style="list-style-type: none"> • <i>The measures taken to ensure sample security.</i> 	<ul style="list-style-type: none"> • Samples are collected on site by NTL personnel, either senior field technician or site geologist, transported to NTL's core and sample handling facility in Waihi. Here samples are prepared for dispatch to the assay laboratory. At night the facility is locked and during the drill programme security patrols used. • Once samples are prepared they are transported the approx. 100m to the SGS assay facility for preparation and analysis. • NTL has a system of order and dispatch numbering for sample tracking. • Once delivered to SGS their protocols for security apply. • Modern drill sampling in the resource areas prior to New Talisman was conducted by reputable mining companies such as Cyprus Mines Corporation, Australian Consolidated Minerals, (Waihi Gold) and Freeport MacRohan and assayed at ALS in Tauranga or SGS in Waihi. There is no evidence from the sample data recorded that there are any issues with data validity or security.
Audits or reviews	<ul style="list-style-type: none"> • <i>The results of any audits or reviews of sampling techniques and data.</i> 	<ul style="list-style-type: none"> • RSG Global reviewed the QAQC procedures for the Talisman project in 2005 and these same procedures. These procedures involve survey control, check sampling, use of standards and blanks and umpire sampling at independent laboratories. This is in addition to assay laboratories own internal QAQC.

Section 2 Reporting of Exploration Results

(Criteria listed in the preceding section also apply to this section.)

Criteria	JORC Code explanation	Commentary
Mineral tenement and land tenure status	<ul style="list-style-type: none"> Type, reference name/number, location and ownership including agreements or material issues with third parties such as joint ventures, partnerships, overriding royalties, native title interests, historical sites, wilderness or national park and environmental settings. The security of the tenure held at the time of reporting along with any known impediments to obtaining a licence to operate in the area. 	<ul style="list-style-type: none"> The mine area is wholly owned by New Talisman Gold Mines Limited under Minerals Mining Permit 51326 which was granted on 03 December 2009 for a term of 25 years and expires on 02 December 2034. The permit area is 299.2 ha and lies within the Kaimai-Mamaku Forest Park which is Crown land administered by the Department of Conservation. The Company operates under an access arrangement with the Minister of Conservation with an authority to enter and operate. In addition, the Company holds a resource consent issued by the District Council to carry out bulk sampling of up to 20,000 m³ per annum. Tenure is secure at time of reporting.
Exploration done by other parties	<ul style="list-style-type: none"> Acknowledgment and appraisal of exploration by other parties. 	<ul style="list-style-type: none"> The Talisman permit area was held as a mining license by NZ Goldfields and predecessors from 1971 to 1992. During this time, they focused on small scale production from 8 level but also completed substantial surface and underground exploration in their own right. They had a number of joint venture partners during the term including, Homestake Mines, Cyprus Mines Corporation, ACM Minerals, and Waihi Gold. Cyprus Mines did the most extensive work driving around 300m further along 8 Level from historic workings and completing 51 drill holes. In 1991 NZ Goldfields went into voluntary liquidation and the mining license was bought by two former directors who formed a private company known as Southern Gold just prior to the mining license expiring.

Criteria	JORC Code explanation	Commentary
Geology	<ul style="list-style-type: none"> <i>Deposit type, geological setting and style of mineralisation.</i> 	<ul style="list-style-type: none"> The Karangahake mineral deposit is a low-sulphidation epithermal gold silver vein system with an overall strike length of around 4km of which approx. 1.5km lies within the NTL mining permit. The deposit comprises several major veins, the most significant of which are the Maria Vein in which the Talisman Mine is developed and the Welcome-Crown Veins. Historic mining has exploited the deposit for around 1km along strike and up to 700m from surface outcrop to the deepest 16 level. Fluid inclusion studies suggest the current highest level of exposure has seen 300m of erosion from the paleosurface.
Drill hole Information	<ul style="list-style-type: none"> <i>A summary of all information material to the understanding of the exploration results including a tabulation of the following information for all Material drill holes:</i> <ul style="list-style-type: none"> <i>easting and northing of the drill hole collar</i> <i>elevation or RL (Reduced Level – elevation above sea level in metres) of the drill hole collar</i> <i>dip and azimuth of the hole</i> <i>down hole length and interception depth</i> <i>hole length.</i> <i>If the exclusion of this information is justified on the basis that the information is not Material and this exclusion does not detract from the understanding of the report, the Competent Person should clearly explain why this is the case.</i> 	<p>New Talisman Gold Mines Ltd has compiled an extensive database of geological and geochemical data for the project from historic data and newly acquired data based on geological mapping, geochemical sampling and surveying that has been used in the development of the resource model.</p> <p>There are a total of 2685 drill hole, recent channel and historic channel collar points in the database and 7117 assay data points. These include 109 drill hole collars and 4100 drill assays, 505 recent channel sample collars and 931 channel assays.</p> <p>Compiled in the following tables are some of the key drill hole sample information.</p> <p>Due to the large amount of data it is impractical to tabulate it all in this set of tables. A full list of the database is appended to the technical report entitled “TALISMAN DEEPS PROJECT, MINERAL RESOURCE POTENTIAL AND ESTIMATES, MINERALS MINING PERMIT 51326”</p> <ul style="list-style-type: none"> Key representative drill hole information is tabulated in the following tables

Data aggregation methods	<ul style="list-style-type: none"><i>In reporting Exploration Results, weighting averaging techniques, maximum and/or minimum grade truncations (eg cutting of high grades) and cut-off grades are usually Material and should be stated.</i>	<ul style="list-style-type: none">Channel samples are recorded as drillholes which along with drillhole data were length weighted down hole.A lower cutoff of 0.5g/t Au was applied to determine significant intersections. Occasionally short intervals below cutoff are																																																																																																																																																																																																																																																																																																																																																					

Criteria	JORC Code explanation	Commentary
	<ul style="list-style-type: none"> Where aggregate intercepts incorporate short lengths of high grade results and longer lengths of low grade results, the procedure used for such aggregation should be stated and some typical examples of such aggregations should be shown in detail. The assumptions used for any reporting of metal equivalent values should be clearly stated. 	<p>incorporated where it not result in the interval overall falling below cutoff.</p> <ul style="list-style-type: none"> Where high grade samples form part of an overall intersection of lower grade material these also reported separately so as not to misrepresent the overall width of intersection of significant grade. For instance; Hole TM002 assayed 2.22g/t Au_equiv over 4.25m and included 0.75m at 4.75g/t Au_equiv. It was decided to use gold equivalent grades and apply these to all samples taken in the modern era as well as the historic samples. This was due to the fact that the 2263 historic channel samples are all expressed in bullion values. We know that from production data gold silver ratios vary considerably and it was not possible to assign arbitrary silver grades to the bullion values with any degree of certainty. With respect to the modern samples that record both gold and silver values it was an easy matter to convert these to gold equivalents using the same gold and silver values that applied at the time of mining in the late 19th and early 20th centuries. The gold price remained constant during the period that recorded production data is available at £4-6s-0d, (£4.25)/oz or USD20.47/oz. Silver values ranged from USD0.49 to USD1.03. An average of USD 0.65 as chosen and a ratio of 0.031609 was factored to give gold equivalence based on the formula $[Au\ g/t + (Ag\ g/t * 0.031609)]$.
Relationship	<ul style="list-style-type: none"> These relationships are particularly important in the reporting of 	<ul style="list-style-type: none"> Only down hole lengths are reported. While generally holes

between mineralisation widths and intercept lengths	<p><i>Exploration Results.</i></p> <ul style="list-style-type: none"> <i>If the geometry of the mineralisation with respect to the drill hole angle is known, its nature should be reported.</i> <i>If it is not known and only the down hole lengths are reported, there should be a clear statement to this effect (eg 'down hole length, true width not known').</i> 	<p>transect the mineralized zones at right angles the downhole intervals can be slightly oblique.</p> <ul style="list-style-type: none"> Differences in down hole intervals and true width are factored into the resource estimate based on the estimation methodology.
Diagrams	<ul style="list-style-type: none"> <i>Appropriate maps and sections (with scales) and tabulations of intercepts should be included for any significant discovery being reported These should include, but not be limited to a plan view of drill hole collar locations and appropriate sectional views.</i> 	<ul style="list-style-type: none"> These are presented in the Public Report that this table accompanies and in the full Talisman Deeps supporting documentation.
Balanced reporting	<ul style="list-style-type: none"> <i>Where comprehensive reporting of all Exploration Results is not practicable, representative reporting of both low and high grades and/or widths should be practiced to avoid misleading reporting of Exploration Results.</i> 	<ul style="list-style-type: none"> All significant results above the cutoff grade of 0.5g/t Au are reported in the tables above and in the accompanying Public Report. All results can be found in the spatial data package that accompanies this Report.
Other substantive exploration data	<ul style="list-style-type: none"> <i>Other exploration data, if meaningful and material, should be reported including (but not limited to): geological observations; geophysical survey results; geochemical survey results; bulk samples – size and method of treatment; metallurgical test results; bulk density, groundwater, geotechnical and rock characteristics; potential deleterious or contaminating substances.</i> 	<ul style="list-style-type: none"> A comprehensive summary a previous exploration results, consultant reviews, geophysics, surface sampling, geological mapping is presented in the accompanying Report. Various metallurgical test work has been carried out that show the ore is amenable to cyanide extraction and not refractory. As the project moves into the bulk sampling phase more metallurgical work will be conducted and the results used to optimize recoveries.
Further work	<ul style="list-style-type: none"> <i>The nature and scale of planned further work (eg tests for lateral extensions or depth extensions or large-scale step-out drilling).</i> <i>Diagrams clearly highlighting the areas of possible extensions, including the main geological interpretations and future drilling areas, provided this information is not commercially sensitive.</i> 	<ul style="list-style-type: none"> Further drill testing and channel sampling to increase the resource is planned. This will involve underground drilling and sampling drives during the bulk sampling programme. This will be part of the feasibility programme that has been initiated with mine support and infrastructure being established currently.

Section 3 Estimation and Reporting of Mineral Resources

(Criteria listed in section 1, and where relevant in section 2, also apply to this section.)

Criteria	JORC Code explanation	Commentary
Database integrity	<ul style="list-style-type: none"> Measures taken to ensure that data has not been corrupted by, for example, transcription or keying errors, between its initial collection and its use for Mineral Resource estimation purposes. Data validation procedures used. 	<ul style="list-style-type: none"> Data was initially captured on paper logs and then entered into excel spreadsheets using standard logging templates to ensure consistency of data capture. Databases have been peer checked on a number of occasions over the duration of the permit. Data validation processes within Excel and in Datamine Studio EM were used during the estimation process.
Site visits	<ul style="list-style-type: none"> Comment on any site visits undertaken by the Competent Person and the outcome of those visits. If no site visits have been undertaken indicate why this is the case. 	<ul style="list-style-type: none"> Mr Stevens has been involved with the project at several stages since 1992 and is familiar with surface geology, underground geology, historic core and NTL drill core. He managed the underground sampling programmes and geological modelling including the historic geology and sample data and is familiar with all aspects of the mine. Mr Chowles has been the General Manager of operations since 2012 and is the author of the reserves statements and prefeasibility studies. He is currently implementing the bulk sampling programme at the mine and is very familiar with all aspects of the project.
Geological interpretation	<ul style="list-style-type: none"> Confidence in (or conversely, the uncertainty of) the geological interpretation of the mineral deposit. Nature of the data used and of any assumptions made. The effect, if any, of alternative interpretations on Mineral Resource estimation. The use of geology in guiding and controlling Mineral Resource estimation. The factors affecting continuity both of grade and geology. 	<ul style="list-style-type: none"> There is enough continuity based on drill hole geology, surface and underground mapping, geophysics and geochemistry to have confidence in the continuity of the geology for areas estimated. Geological interpretation of the Maria Vein and the ore zones within it have been determined by compiling all mapping and drill hole data completed by NTL and by detailed digitizing of georeferenced historic mine plans including vein positions and mapped widths, including faults on a level by level basis. The Competent Person has reviewed alternative geological

Criteria	JORC Code explanation	Commentary
		<p>interpretations and these are not considered to have any adverse impact on the MRE.</p> <ul style="list-style-type: none"> • The geology has formed the basis to create domains to constrain the MRE process. • Vein positions and variability were checked against several of the levels where NTL had its own data to check consistency. • This was used as the basis for constructing sections at 10m and 20m intervals along strike interpreting the position and vein thickness of the Maria Vein along its known strike length. • These were then wireframed to and verified to form enclosed vein models suitable for estimation purposes. • Historic data points had been previously captured by Ian Brown and associates in the late 1980s. These data were converted to NZMG coordinates and imported into Datamine Studio EM software. Their positions were checked against digital stope plans and against historic long sections of stope plans showing the raise sample positions. • Position adjustments were made to ensure data points lay on the raise positions within the model. This included re-projecting channel collar positions onto the vein wireframe • The Competent Person has reviewed alternative geological interpretations and these are not considered to have any adverse impact on the MRE • The geology has formed the basis to create domains to constrain the MRE process
Dimensions	<ul style="list-style-type: none"> • <i>The extent and variability of the Mineral Resource expressed as</i> 	<ul style="list-style-type: none"> • The Maria Vein model is over 1300m long and has been extended to

Criteria	JORC Code explanation	Commentary										
	<i>length (along strike or otherwise), plan width, and depth below surface to the upper and lower limits of the Mineral Resource.</i>	<p>depths ranging from 200 to over 300m below sea level.</p> <ul style="list-style-type: none">This is on the basis of locating and plotting drill hole data from the early 20th century where, although there is no assay data, there is detailed geology showing positions of the Maria Vein at least 100m below 15 Level.										
Estimation and modelling techniques	<ul style="list-style-type: none"><i>The nature and appropriateness of the estimation technique(s) applied and key assumptions, including treatment of extreme grade values, domaining, interpolation parameters and maximum distance of extrapolation from data points. If a computer assisted estimation method was chosen include a description of computer software and parameters used.</i><i>The availability of check estimates, previous estimates and/or mine production records and whether the Mineral Resource estimate takes appropriate account of such data.</i><i>The assumptions made regarding recovery of by-products.</i><i>Estimation of deleterious elements or other non-grade variables of economic significance (eg sulphur for acid mine drainage characterisation).</i><i>In the case of block model interpolation, the block size in relation to the average sample spacing and the search employed.</i><i>Any assumptions behind modelling of selective mining units.</i><i>Any assumptions about correlation between variables.</i><i>Description of how the geological interpretation was used to control the resource estimates.</i><i>Discussion of basis for using or not using grade cutting or capping.</i><i>The process of validation, the checking process used, the comparison</i>	<ul style="list-style-type: none">The wireframe models of the Maria Vein were filled with 10m by 10m by vein width blocks utilizing sub-cell splitting.Variography determined that that an anisotropic semi variogram model with a range of 12m along strike and 36m on the dip of the vein was appropriate.Variography determined that the search ellipsoid was best oriented at -60 degrees +/- 20 degrees. This corresponds to visually determined trends in the orientation of known high grade shoots.An overall wireframe model for the Maria Vein was produced but, based on geology, has been subdivided into 3 separate geological domains that correlate with the Dubbo Zone, the Talisman-Bonanza Zone and the Woodstock Zone. These domains were constructed and estimated separately.These wireframes were then filled with block model cells orientated orthogonally. And the following estimation parameters applied. <table><tr><th>Block Model And Estimation Parameters</th><th>Model And Estimation Parameter Values</th></tr><tr><td>Parent Block Block Cell Size</td><td>10m x 10m x vein width</td></tr><tr><td>Sub Cell Splitting</td><td>Auto fill to maximum of 5m x 5m x vein width</td></tr><tr><td>Estimation Method</td><td>Ordinary kriging and Inverse Distance Squared</td></tr><tr><td>Density</td><td>2.53 t/m³</td></tr></table>	Block Model And Estimation Parameters	Model And Estimation Parameter Values	Parent Block Block Cell Size	10m x 10m x vein width	Sub Cell Splitting	Auto fill to maximum of 5m x 5m x vein width	Estimation Method	Ordinary kriging and Inverse Distance Squared	Density	2.53 t/m ³

factors or assumptions	<i>mining dimensions and internal (or, if applicable, external) mining dilution. It is always necessary as part of the process of determining reasonable prospects for eventual economic extraction to consider potential mining methods, but the assumptions made regarding mining methods and parameters when estimating Mineral Resources may not always be rigorous. Where this is the case, this should be reported with an explanation of the basis of the mining assumptions made.</i>	<p>prefeasibility study in 2013 by constructing wireframe strings around the geological block model encompassing the economic portions of the Resource as known at that time. Waste material necessary to the extraction process was included in the wireframes; the resultant wireframe was evaluated against the applicable block model to determine volume and metal content.</p> <ul style="list-style-type: none"> • An option analysis identified sub-level stoping as the most appropriate mining method which offers the flexibility to adapt to both mechanised and traditional drill and blast techniques. • Excavations required to access each zone, appropriate to the intended method, has been designed inclusive of drives, traveling ways and ventilation passes. • This deposit is a narrow vein gold deposit. Maximum stope span has been limited to 35m. Strike and dip pillars have been designed to a hydraulic radius of 1.4 which is well above the existing HR of 0.9 observed in stable pillars immediately adjacent to the planned stopes. • The Mineral Resource model is described in the first section of this table. • Dilution necessary to removal of ore has not been determined for this new resource estimate and will be as part of the feasibility study. • The resource modelling process includes some dilution as some blocks include wall rock material. • No minimum mining widths have been applied as all veins modelled are equal to, or exceed 1.0m in width which is acceptable for removal by the envisaged mining method. • Visual inspection of existing stopes indicates that stope widths of <0.6m are attainable within this environment.
Metallurgical	• <i>The basis for assumptions or predictions regarding metallurgical</i>	• Detailed metallurgical studies to date show that expected recoveries

Criteria	JORC Code explanation	Commentary
factors or assumptions	<i>amenability. It is always necessary as part of the process of determining reasonable prospects for eventual economic extraction to consider potential metallurgical methods, but the assumptions regarding metallurgical treatment processes and parameters made when reporting Mineral Resources may not always be rigorous. Where this is the case, this should be reported with an explanation of the basis of the metallurgical assumptions made.</i>	<p>are likely to equal or exceed 95%.</p> <ul style="list-style-type: none"> The deposit is typical of the low sulphidation deposits in the Waihi Gold District which are by and large amenable to direct cyanidation, gravity separation of free gold and/or flotation concentrate cyanidation. There is no evidence at this stage of any deleterious minerals that would impact on processing.
Environmental factors or assumptions	<ul style="list-style-type: none"> <i>Assumptions made regarding possible waste and process residue disposal options. It is always necessary as part of the process of determining reasonable prospects for eventual economic extraction to consider the potential environmental impacts of the mining and processing operation. While at this stage the determination of potential environmental impacts, particularly for a greenfields project, may not always be well advanced, the status of early consideration of these potential environmental impacts should be reported. Where these aspects have not been considered this should be reported with an explanation of the environmental assumptions made.</i> 	<ul style="list-style-type: none"> The deposit lies on DOC land under MP51326 granted to New Talisman Gold Mines Ltd. Consents for bulk sampling up to 20,000m³/annum have been granted for an initial 2 year period once bulk sampling commences. The local authorities have consented small and large scale mining projects in the District over the last 25 years including NTL's Talisman project in 2013. Provided the Company prepares sufficient environmental data to back up any development proposal it will be dealt with by the authorities on its merits.
Bulk density	<ul style="list-style-type: none"> <i>Whether assumed or determined. If assumed, the basis for the assumptions. If determined, the method used, whether wet or dry, the frequency of the measurements, the nature, size and representativeness of the samples.</i> <i>The bulk density for bulk material must have been measured by methods that adequately account for void spaces (vugs, porosity, etc), moisture and differences between rock and alteration zones within the deposit.</i> <i>Discuss assumptions for bulk density estimates used in the evaluation process of the different materials.</i> 	<ul style="list-style-type: none"> The bulk dry density used in the estimate is 2.53g.cm⁻³. This is based on 211 determinations of vein and wall rock samples. These were sorted into 41 vein samples that had a dry density of 2.53g.cm³. All densities were determined on a wet, dry and particle density basis by the University of Auckland Geology Department and took into account voids and porosity.
Classification	<ul style="list-style-type: none"> <i>The basis for the classification of the Mineral Resources into varying</i> 	<ul style="list-style-type: none"> The models were run using the search parameters described in the

Criteria	JORC Code explanation	Commentary
n	<p><i>confidence categories.</i></p> <ul style="list-style-type: none"> <i>Whether appropriate account has been taken of all relevant factors (ie relative confidence in tonnage/grade estimations, reliability of input data, confidence in continuity of geology and metal values, quality, quantity and distribution of the data).</i> <i>Whether the result appropriately reflects the Competent Person's view of the deposit.</i> 	<p>preceding sections.</p> <ul style="list-style-type: none"> Measured Resources were applied to the first pass search parameters, although it was decided to only apply the Measured and Indicated categories to areas where NTL's data only was used. While the data density for the historic data is sufficiently closely spaced to be considered measured, due to the uncertainty around QAQC it was decided to class this as Inferred. Indicated resources were determined a 2 times the search ellipsoid and Inferred at 3 times. The model was rerun using the extents of the wireframe to determine mineral inventory or geological potential beyond the measured, indicated and inferred resource extents.ie areas within the geological model that with further exploration could be upgraded to fall within an appropriate resource category. This geological potential constitutes an Exploration Target as defined in the JORC code 2012 and any resource potential may not be realized in part or in whole. In the view of the Competent person this fairly represents the data and is considered conservative.
Audits or reviews	<ul style="list-style-type: none"> <i>The results of any audits or reviews of Mineral Resource estimates.</i> 	<ul style="list-style-type: none"> The report and data has been peer reviewed by NTL and an independent geological consultancy.
Discussion of relative accuracy/ confidence	<ul style="list-style-type: none"> <i>Where appropriate a statement of the relative accuracy and confidence level in the Mineral Resource estimate using an approach or procedure deemed appropriate by the Competent Person. For example, the application of statistical or geostatistical procedures to quantify the relative accuracy of the resource within stated confidence limits, or, if such an approach is not deemed appropriate, a qualitative discussion of the factors that could affect the relative accuracy and confidence of the estimate.</i> 	<ul style="list-style-type: none"> Primary assessment of the accuracy of this estimate has been quantified through applying the results of the estimate to the historically mined areas. The results indicate historic depletions at an average grade of 28.31 g/t Au which is consistent with results reported from the mines production results of 27.1g/t Au This estimate is a global estimate..

Criteria	JORC Code explanation	Commentary
	<ul style="list-style-type: none"> <i>The statement should specify whether it relates to global or local estimates, and, if local, state the relevant tonnages, which should be relevant to technical and economic evaluation. Documentation should include assumptions made and the procedures used.</i> <i>These statements of relative accuracy and confidence of the estimate should be compared with production data, where available.</i>
